GPU Computing and Programming

Instructor: Andreas W. Götz

Date: August 5, 2021
Location: Main Room Session

Training overview

We will cover the following topics

- GPU hardware overview
- GPU accelerated software examples
- GPU enabled libraries
- CUDA C programming basics

  – 15 minutes break –
- Accessing GPU nodes and running GPU jobs on SDSC Expanse
- Hands-on exercises on SDSC Expanse – CUDA
- OpenACC introduction
- Hands-on exercises on SDSC Expanse – OpenACC

What is a GPU?

Accelerator

- Specialized hardware component to speed up some aspect of a computing workload.
- Examples include floating point co-processors in older PCs, specialized chips to perform floating point math in hardware rather than software. More recently, Field Programmable Gate Arrays (FPGAs).

Graphics processing unit

- “Specialist” processor to accelerate the rendering of computer graphics.
- Development driven by $150 billion gaming industry.
- Originally fixed function pipelines.
- Modern GPUs are programmable for general purpose computations (GPGPU).
- Simplified core design compared to CPU
  - Limited architectural features, e.g. branch caches
  - Partially exposed memory hierarchy

Tseng Labs ET4000/W32p 1991

Voodoo3 2000 AGP card 1999

GeForce 6600 GT Personal Cinema 2004

NVIDIA GeForce GTX 280 2008

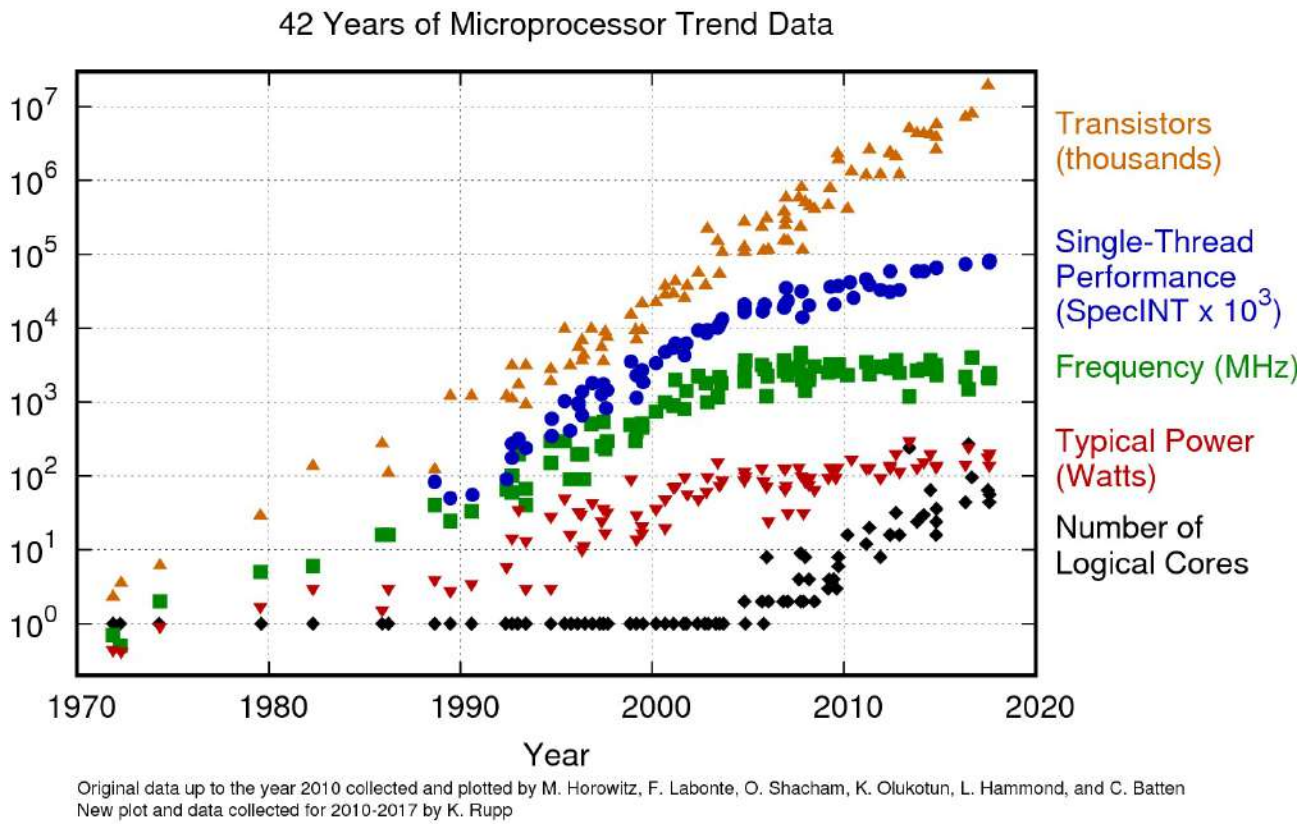
Why is there such an interest in GPUs?

Moore's law

- Transistor count in integrated circuits doubles about every two years.
- Exponential growth still holds (see figure).
- However…

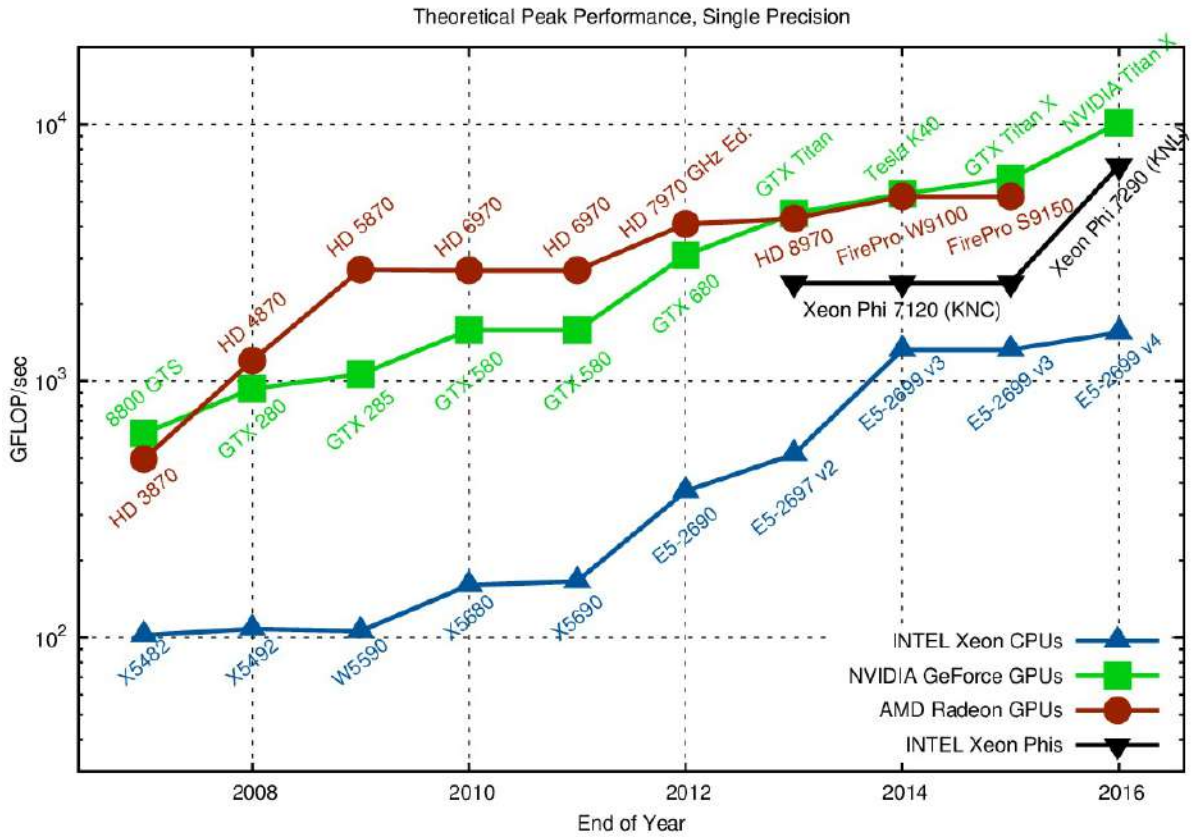
Trends since mid 2000s

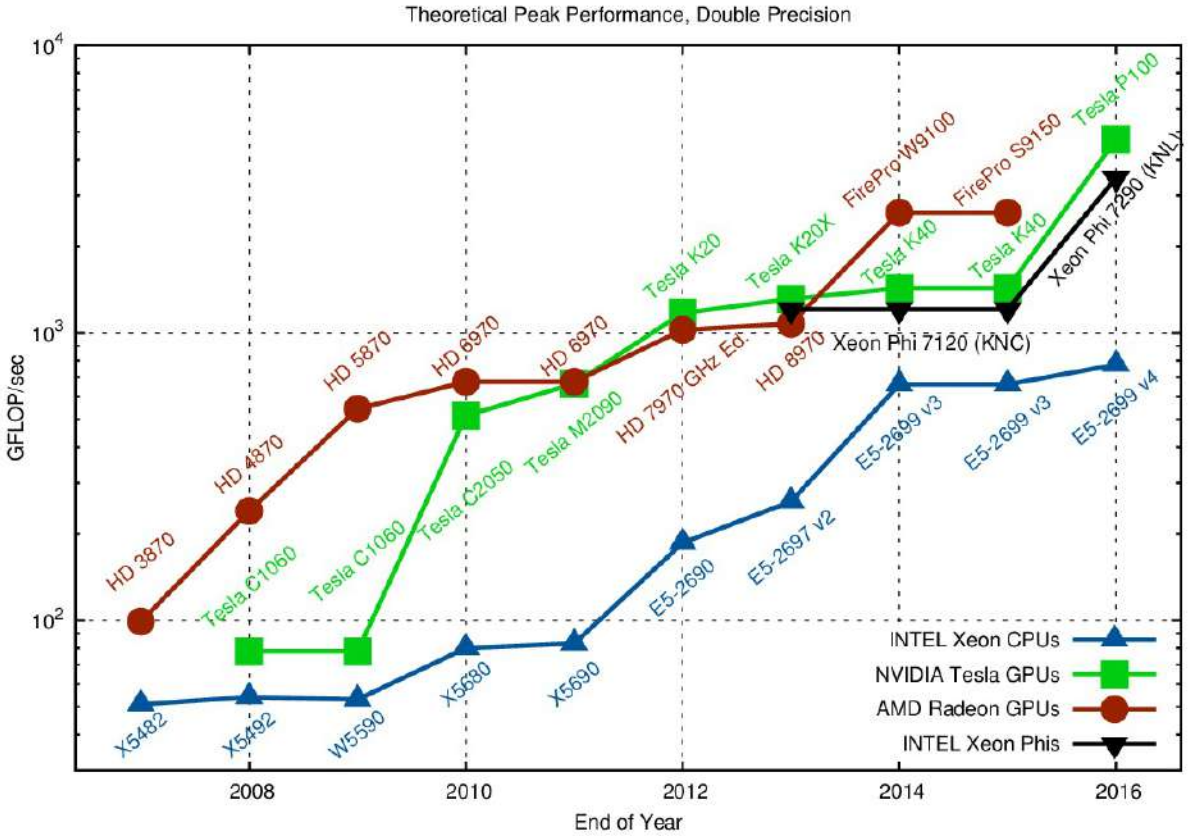
- Clock frequency constant.
- Single CPU core performance (serial execution) roughly constant.
- Performance increase due to increase of CPU cores per processor.
- Cannot simply wait two years to double code execution performance.
- Must write parallel code.



Source: https://www.karlrupp.net/2018/02/42-years-of-microprocessor-trend-data/

Why is there such an interest in GPUs?

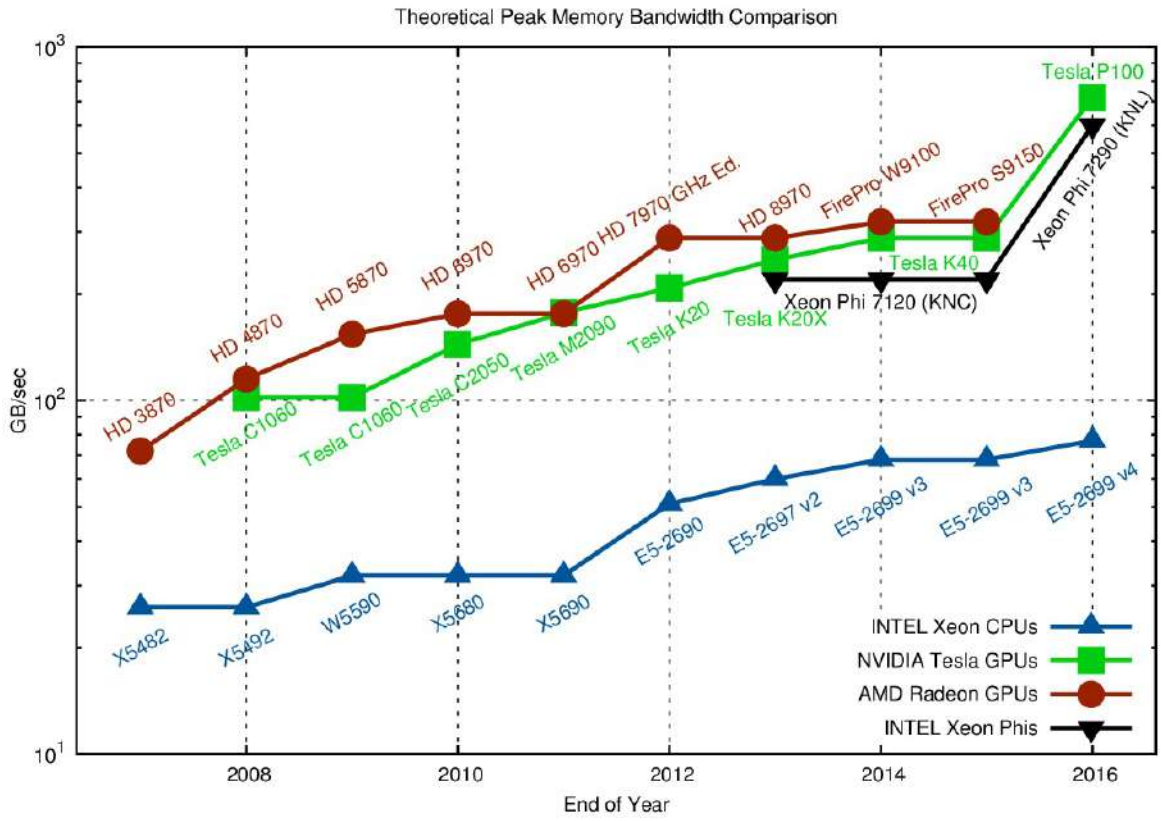


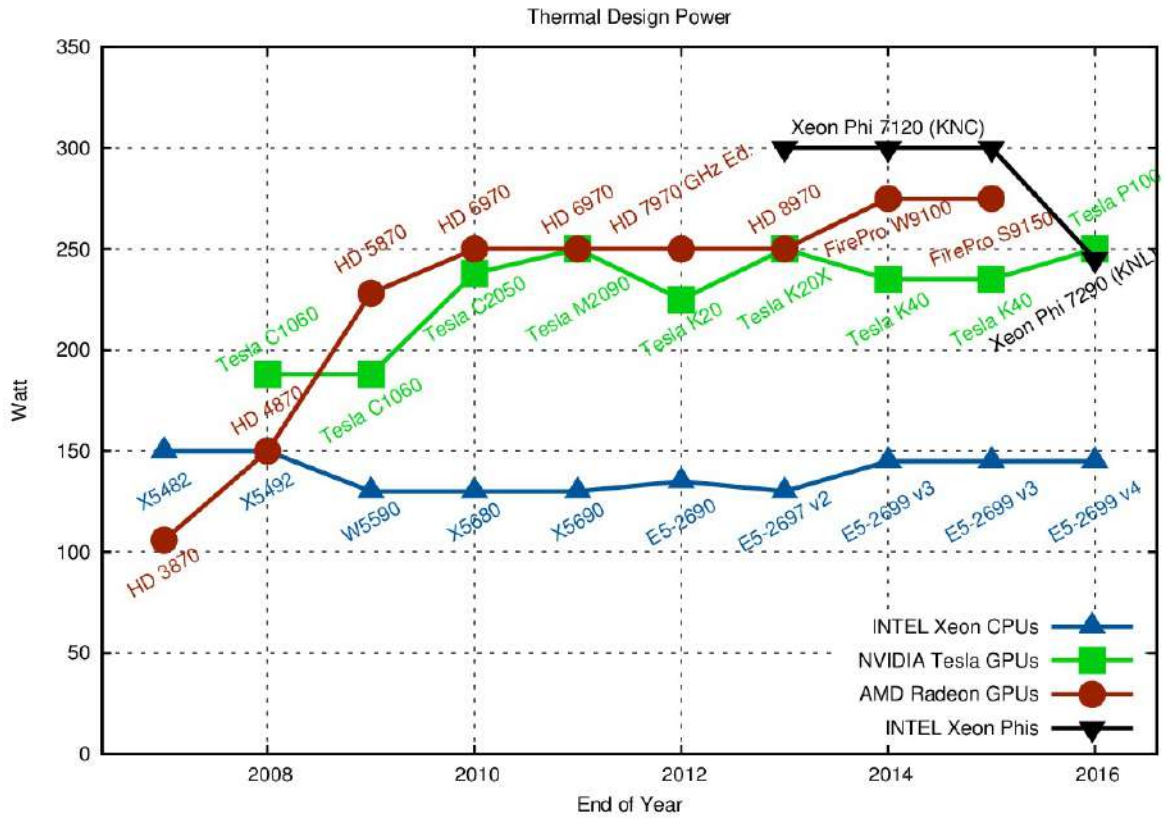


- GPUs offer significantly higher 32-bit floating point performance than CPUs.
- Datacenter GPUs also offer significantly higher 64-bit floating point performance than CPUs.

Figures source: https://www.karlrupp.net/2013/06/cpu-gpu-and-mic-hardware-characteristics-over-time/

Why is there such an interest in GPUs?

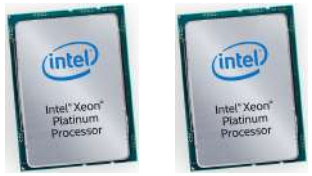




- GPUs have significantly higher memory bandwidth than CPUs.
- Given power consumption, a fair comparison would be a single GPU to 2-socket CPU server.

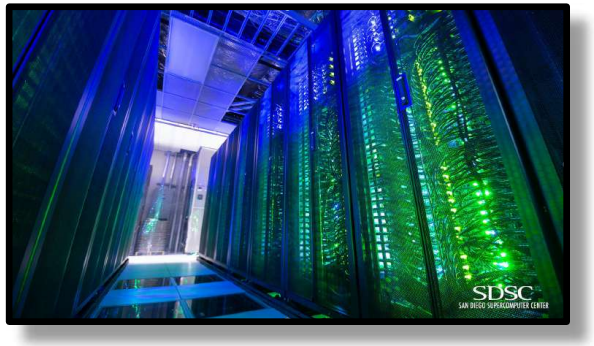
Figures source: https://www.karlrupp.net/2013/06/cpu-gpu-and-mic-hardware-characteristics-over-time/

Comparison of top (in 2018) X86 CPU vs Nvidia V100 GPU



Aggregate performance numbers (FLOPs, BW)	**Dual socket Intel 8180 28-core (56 cores per node)**	**Nvidia Tesla V100, dual cards in an x86 server**
Peak DP FLOPs	4 TFLOPs	14 TFLOPs (3.5x)
Peak SP FLOPs	8 TFLOPs	28 TFLOPs (3.5x)
Peak HP FLOPs	N/A	224 TFLOPs
Peak RAM BW	~ 200 GB/sec	~ 1,800 GB/sec (9x)
Peak PCIe BW	N/A	32 GB/sec
Power / Heat	~ 400 W	2 x 250 W (+ ~ 400 W for server) (~ 2.25x)
Purchase cost	$20,000 USD	$20,000 USD
Code portable?	Yes	Yes (OpenACC, OpenCL)

A supercomputer in a desktop?



ASCI White (LLNL)

- **12.3 TFLOP/sec** – #1 Top 500, November 2001.
- Cost – $110 Million USD (in 2001!)

SDSC Expanse

- 728 CPU nodes with 4.6 TFLOP/sec (each node)
  3.4 PFLOP/sec (aggregate CPU)
- 52 GPU nodes 4 x Nvidia V100 (Volta arch)
  31.3 TFLOP/sec DP, 62.7 TFLOP/sec SP (each node)
  1.6 PFLOP/sec DP, 3.3 PFLOP/sec SP (aggregate GPU)
- Hardware Cost – $10 Million USD

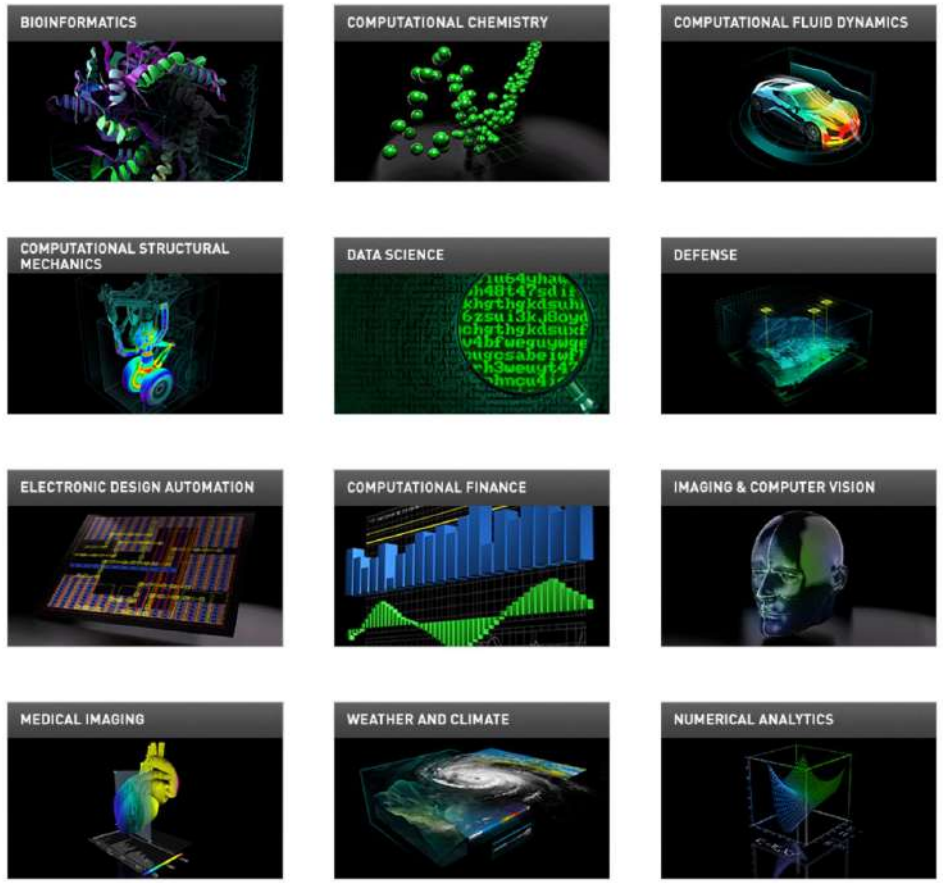
DIY 4 x Nvidia RTX 3080 box (2020) (Ampere arch)

- 1.9 TFLOP/sec DP
- **119.0 TFLOP/sec SP**
- Cost – ~ $4 Thousand USD

GPU accelerated software

Examples from virtually any field

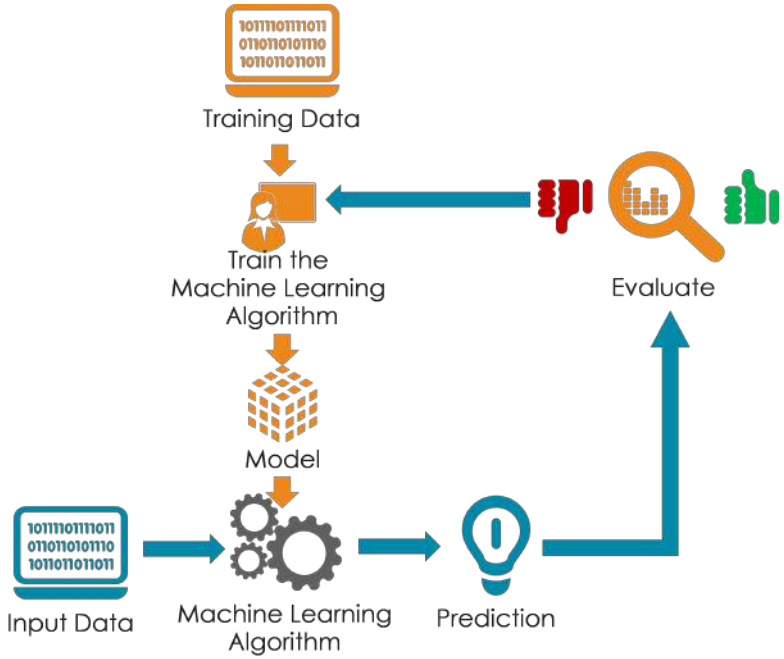
- Exhautive list on https://www.nvidia.com/en-us/data-center/gpu-accelerated-applications/
- Chemistry
- Life sciences
- Bioinformatics
- Astrophysics
- Finance
- Medical imaging
- Natural language processing
- Social sciences
- Weather and climate
- Computational fluid dynamics
- **Machine learning**, of course
- etc...



Machine learning and GPUs

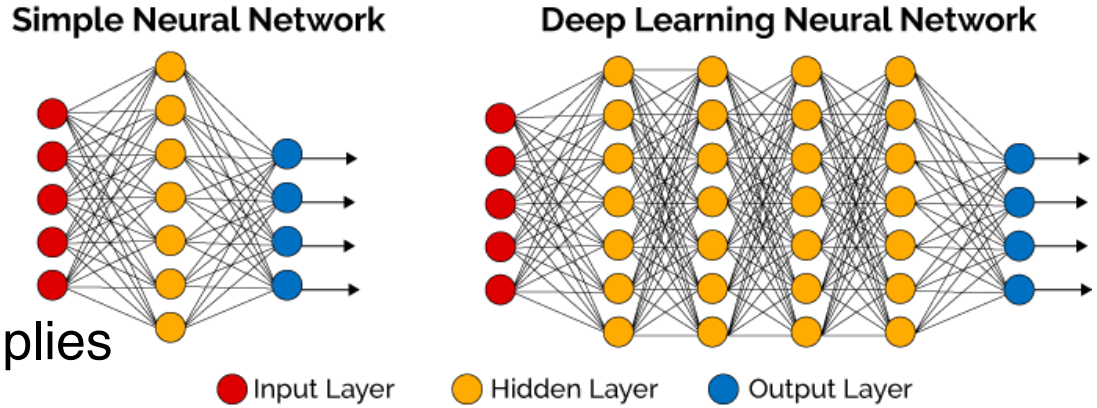
Machine learning

- Estimate / predictive model based on reference data.
- Many different methods and algorithms.
- GPUs are particularly well suited for deep learning workloads

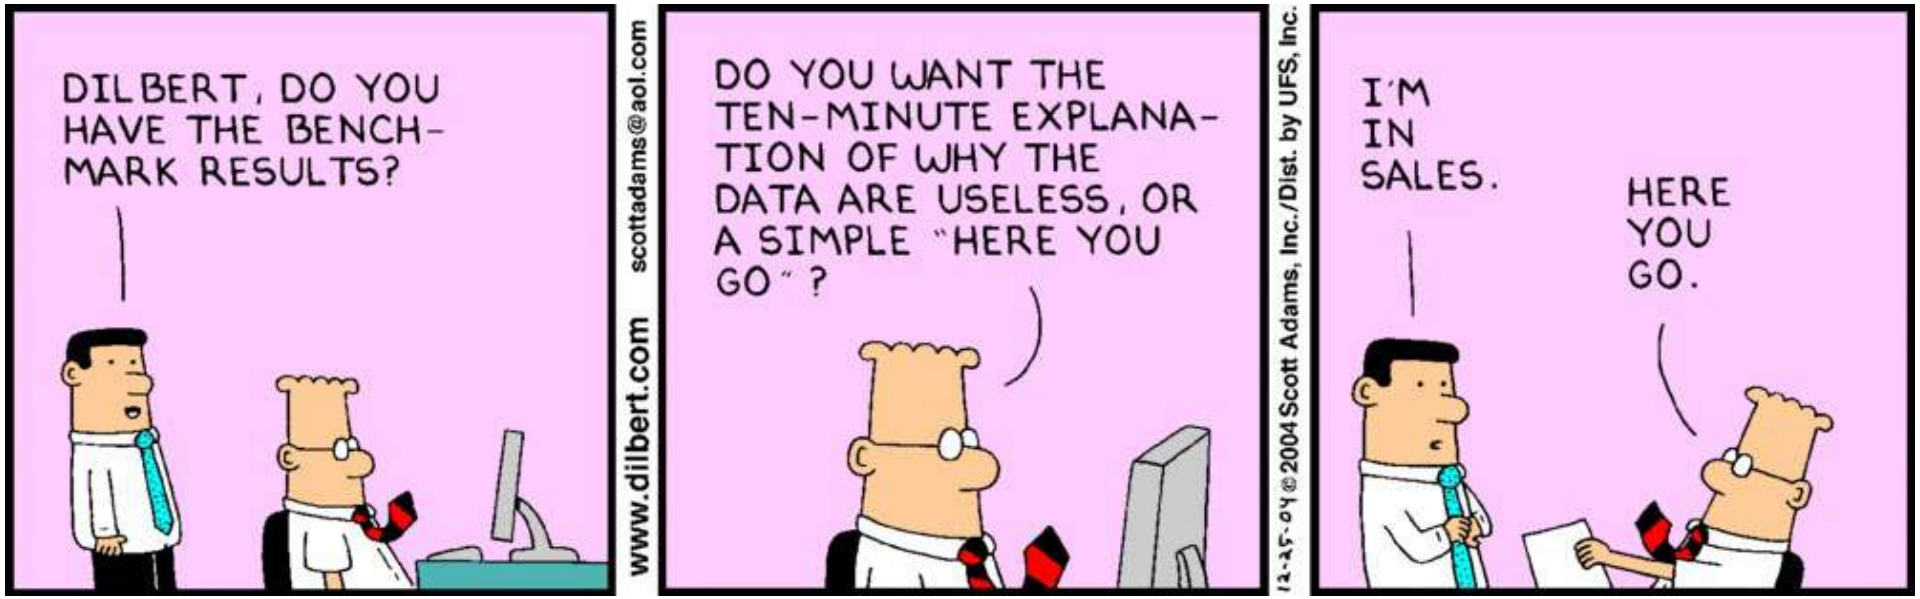


Deep learning

- Neural networks with many hidden layers.
- Tensor operations (matrix multiplications).
- GPUs are very efficient at these (4x4 matrix algebra is used in 3D graphics)
- Half-precision arithmetic can be used for many ML applications, at least for inference.
- Nvidia Volta architecture introduced tensor cores, dedicated hardware for mixed-precision matrix multiplies
- ML frameworks provide GPU support (E.g. PyTorch, TensorFlow)



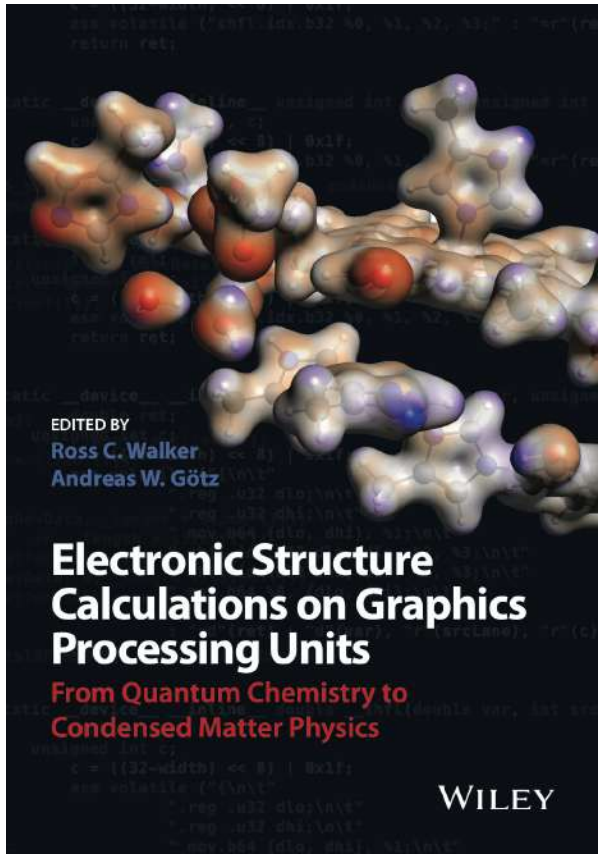
Benchmark examples

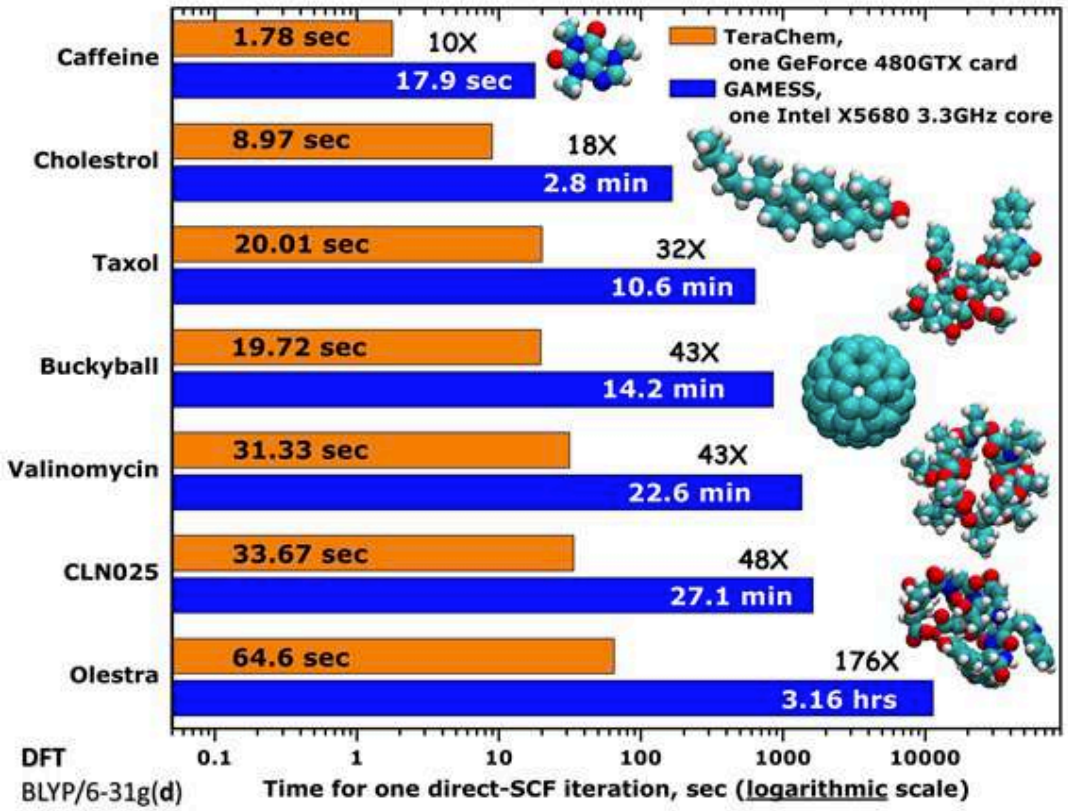


Benchmark examples

Quantum chemistry

- Compute molecular properties from quantum mechanics (TeraChem code)

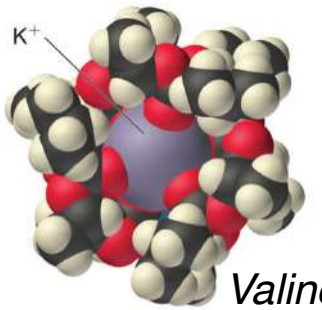




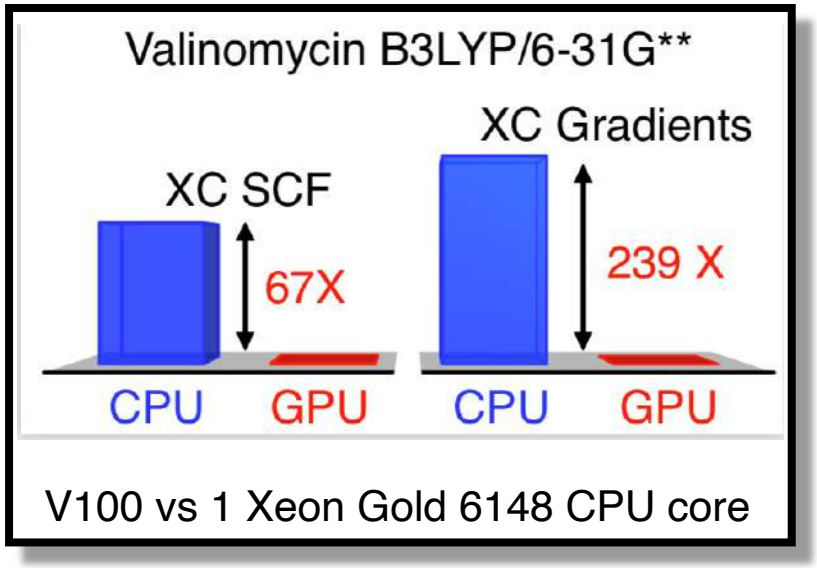
Benchmark examples

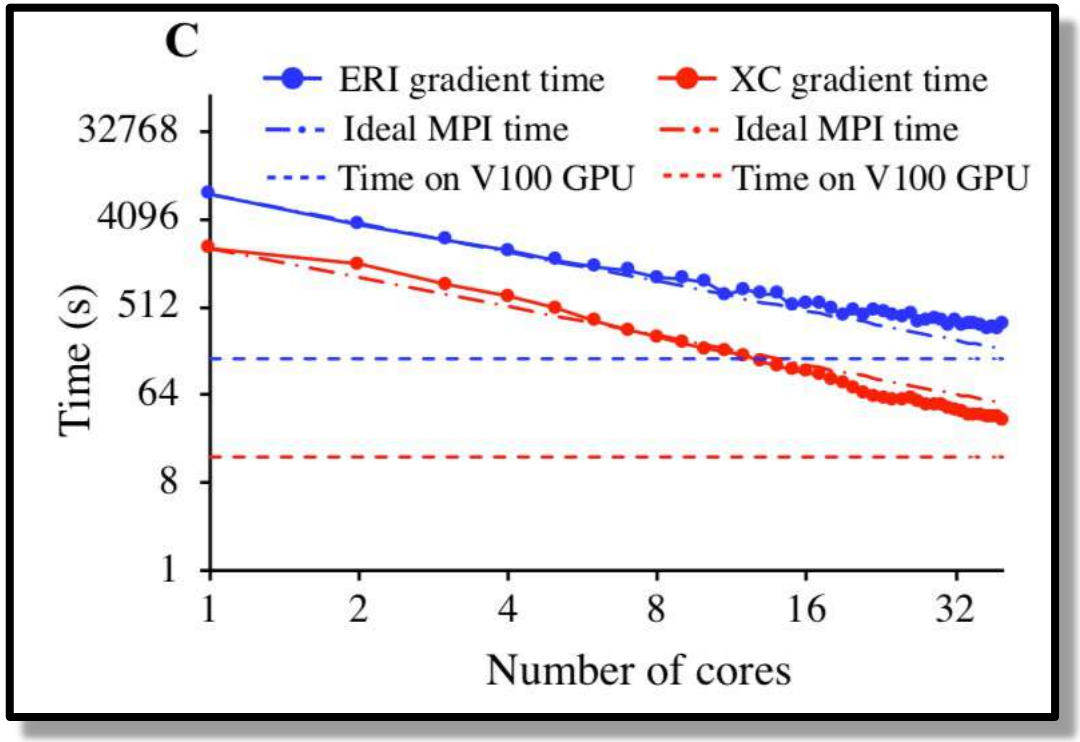
Quantum chemistry

- Compute molecular properties from quantum mechanics
- Example: QUICK code (open source, developed by Merz and Goetz labs)
- https://github.com/merzlab/QUICK



Valinomycin





See *J. Chem. Theory Comput.* **16**, 4315-4326 (2020)
https://dx.doi.org/10.1021/acs.jctc.0c00290

Benchmark examples

$$E[\rho] = T_s[\rho] + \int d\mathbf{r}\rho(\mathbf{r})v_{ext}(\mathbf{r}) + \frac{1}{2}\int d\mathbf{r}d\mathbf{r}'\frac{\rho(\mathbf{r})\rho(\mathbf{r}')}{|\mathbf{r}-\mathbf{r}'|} + E_{xc}[\rho]$$

QUICK Density Functional Theory

- Numerical quadrature of exchange-correlation potential and energy

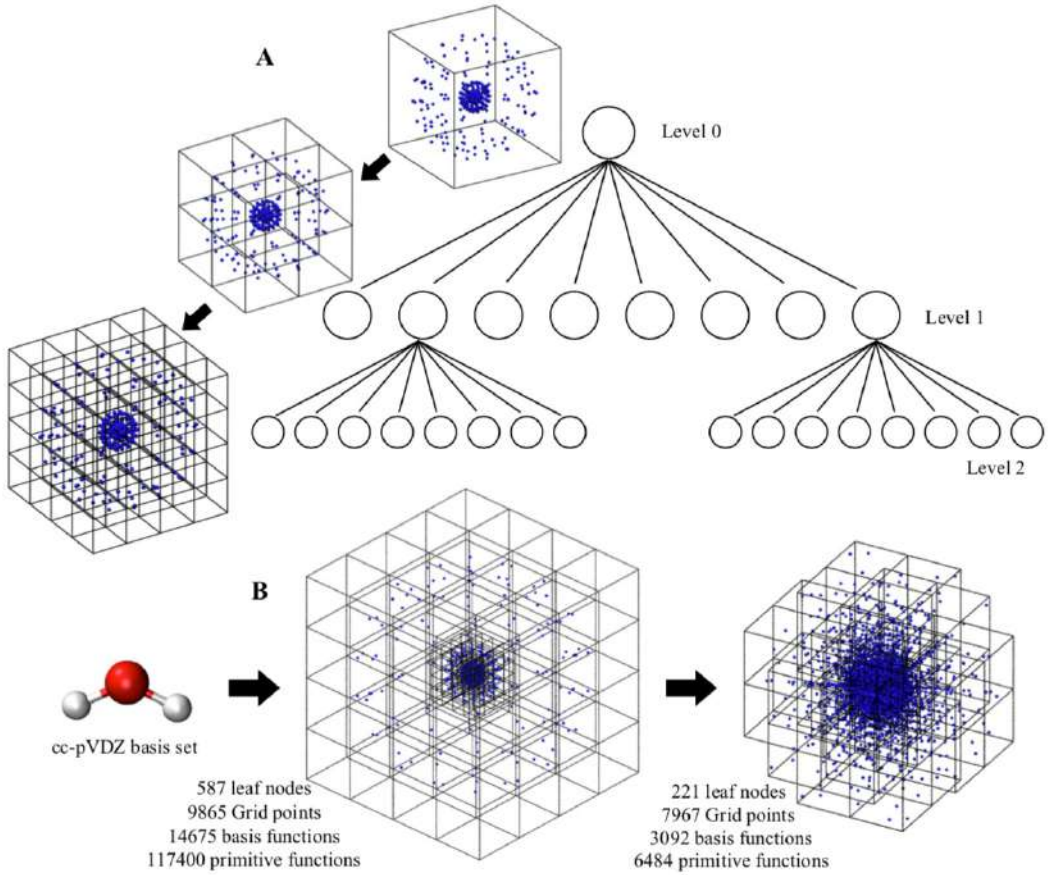
$$E^{xc} = \int f(\rho_\alpha, \rho_\beta, \gamma_{\alpha\alpha}, \gamma_{\alpha\beta}, \gamma_{\beta\beta})dr,$$

$$\int d\mathbf{r} f(\mathbf{r}) \approx \sum_i \omega_i f(\mathbf{r}_i)$$

- See *J. Chem. Theory Comput.* **16**, 4315-4326 (2020) https://dx.doi.org/10.1021/acs.jctc.0c00290

Parallel numerical quadrature

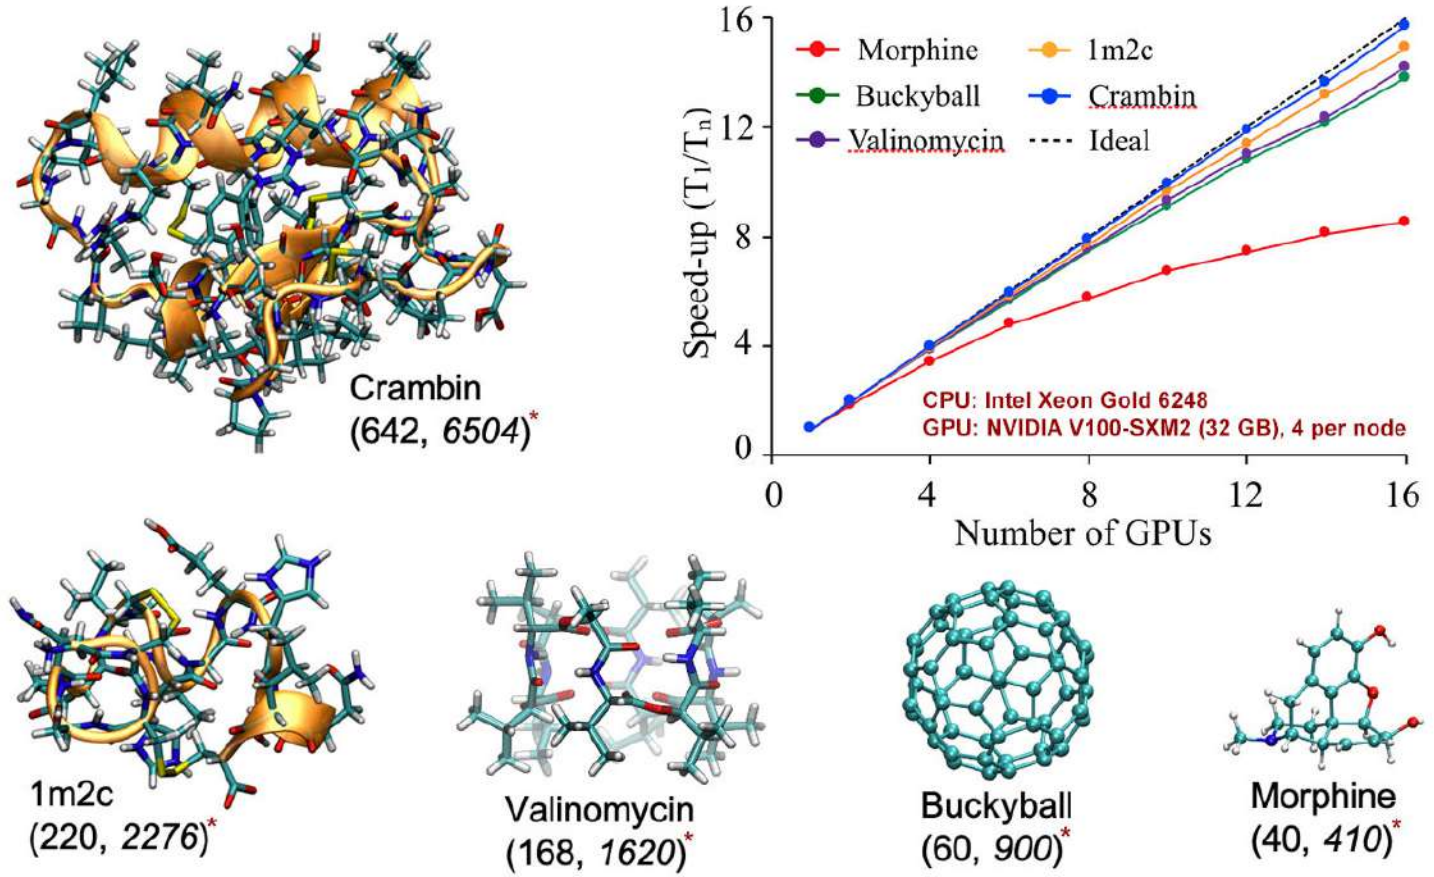
- Octree based partitioning of 3D grid points
- Prescreening of function values on grid point batches leads to linear scaling for large molecules
- Grid point batches are processed in parallel on CPU cores via MPI or GPUs via CUDA.



Benchmark examples

QUICK Multi-GPU Scaling

- See *J. Chem. Theory Comput.* **17**, 3955–3966 (2021), https://doi.org/10.1021/acs.jcim.1c00169

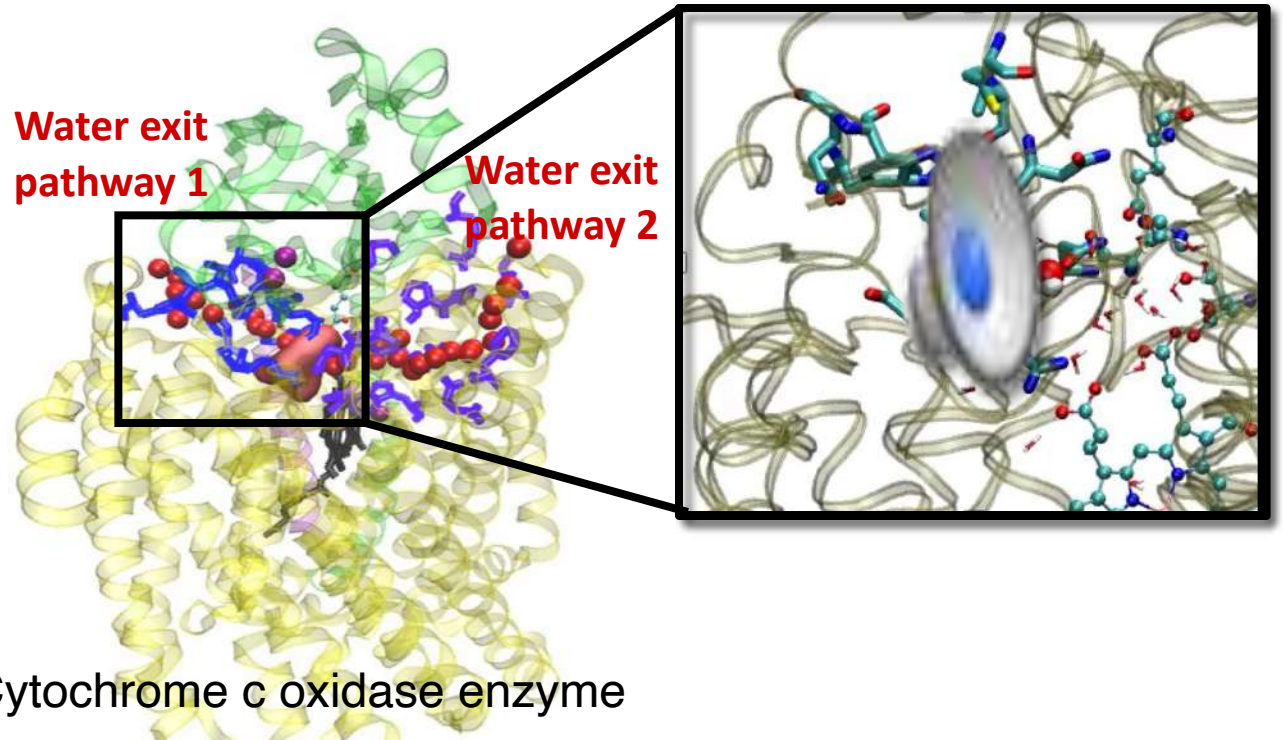


** The number of atoms and number of basis functions are given in brackets.*

Benchmark examples

Molecular dynamics

- Amber code: Atomistic simulations of condensed phase biomolecular systems



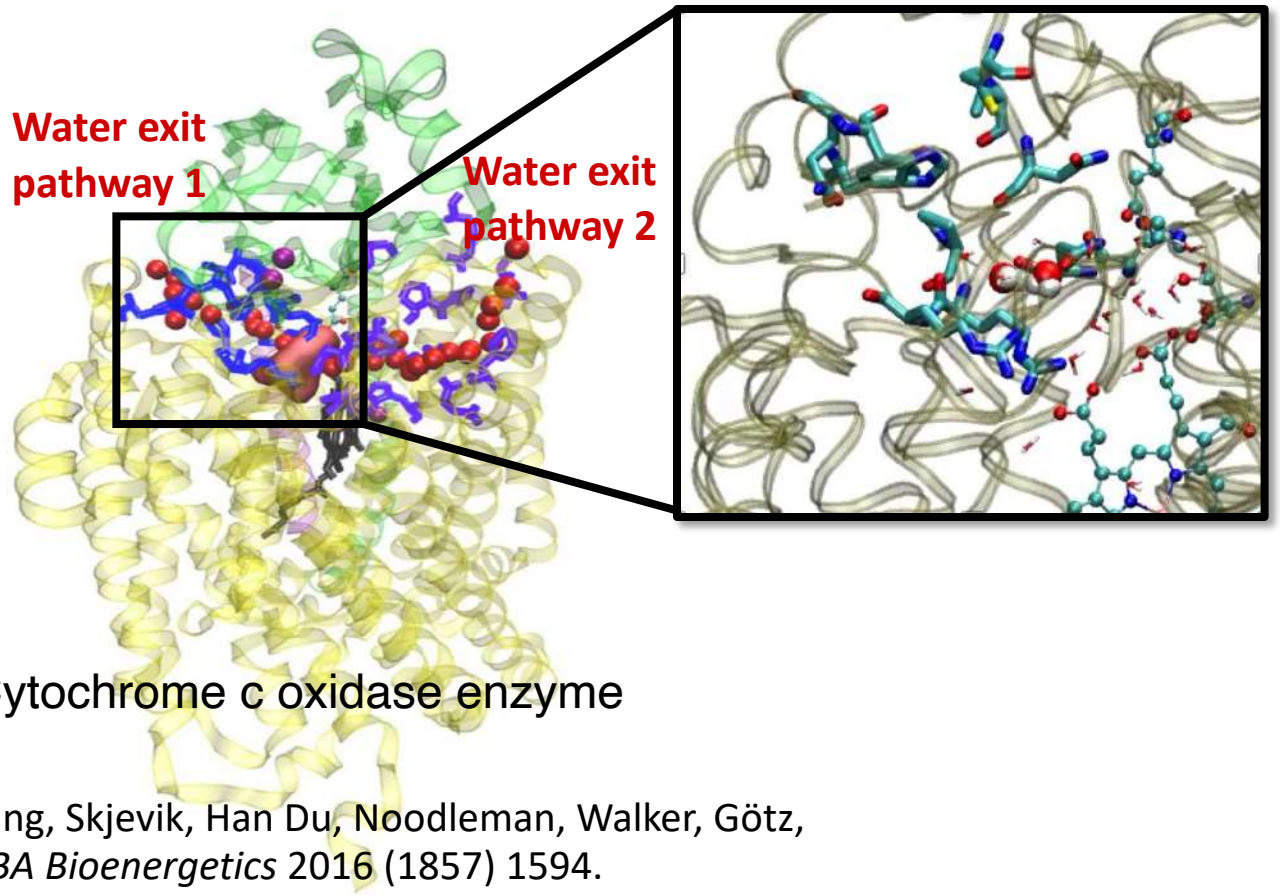
Cytochrome c oxidase enzyme

Yang, Skjevik, Han Du, Noodleman, Walker, Götz,
BBA Bioenergetics 2016 (1857) 1594.

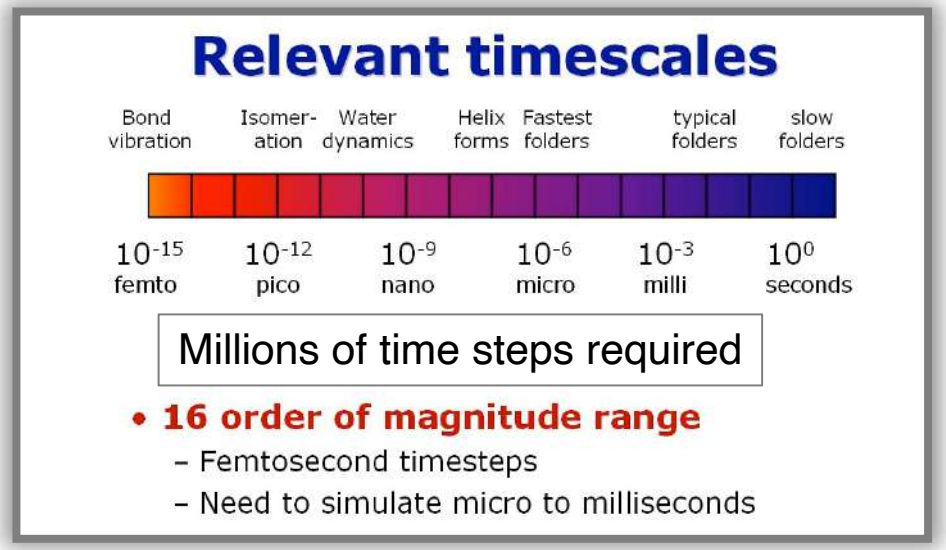
Benchmark examples

Molecular dynamics

- Amber code: Atomistic simulations of condensed phase biomolecular systems



Cytochrome c oxidase enzyme

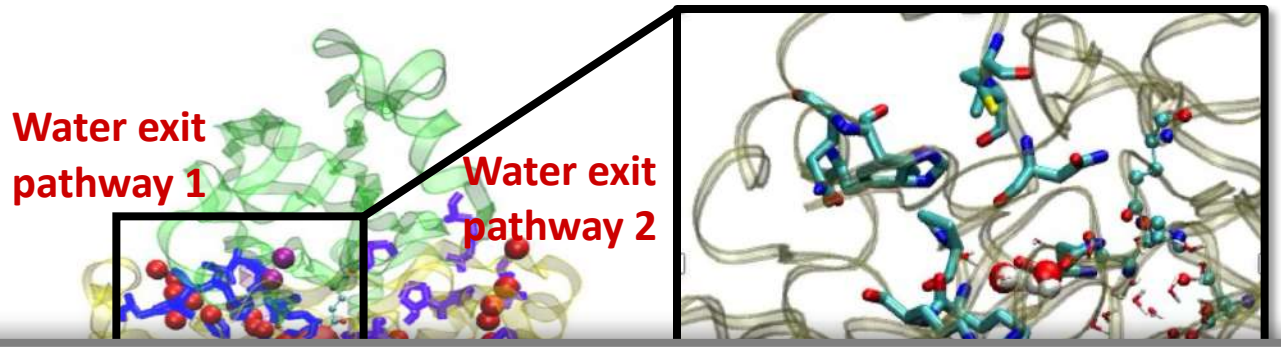


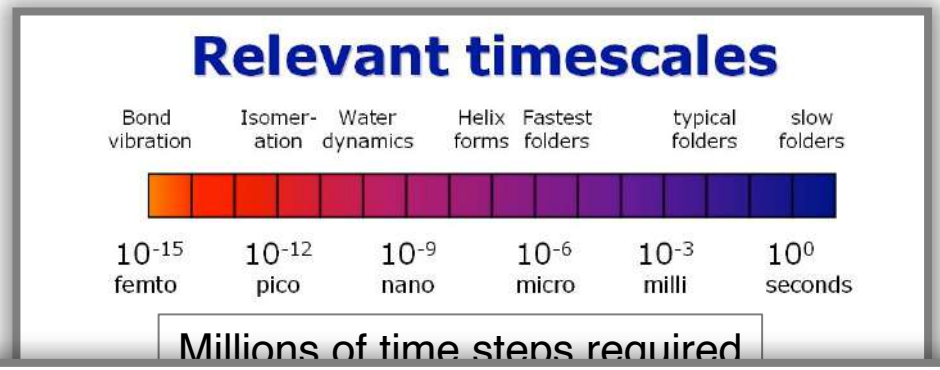
Yang, Skjevik, Han Du, Noodleman, Walker, Götz,
BBA Bioenergetics 2016 (1857) 1594.

Benchmark examples

Molecular dynamics

- Amber code: Atomistic simulations of condensed phase biomolecular systems



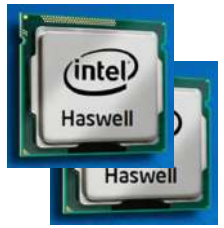


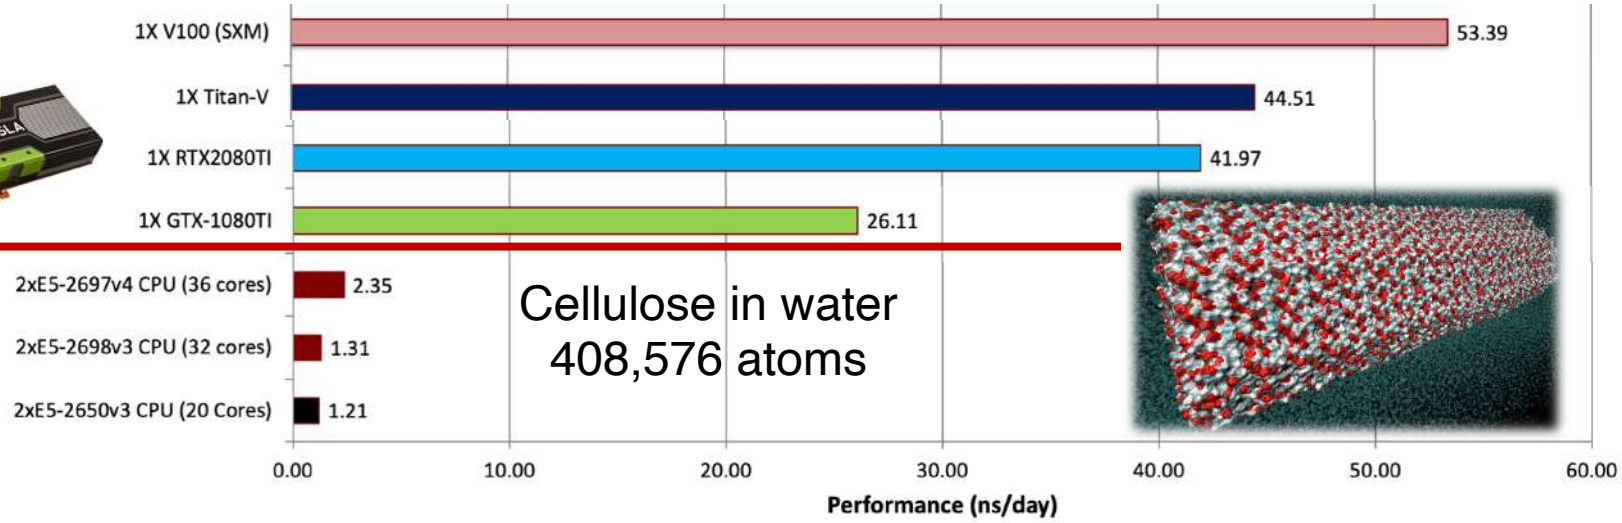
Amber 18 molecular dynamics software

Götz, Williamson, Xu, Poole, Le Grand, Walker, *J Chem Theory Comput* 2012 (8) 1542.

Le Grand, Götz, Walker, *Comput Phys Comm* 2013 (184) 374.

Salomon-Ferrer, Götz, Poole, Le Grand, Walker, *J Chem Theory Comput* 2012 (8) 1542.



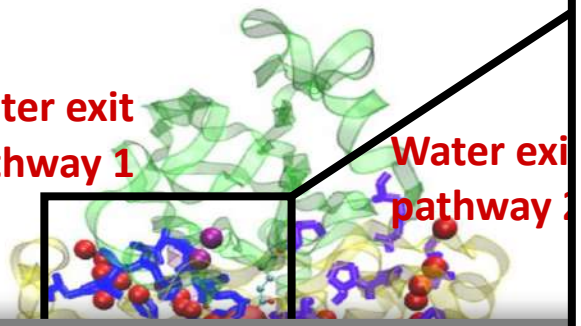


Cellulose in water
408,576 atoms

Benchmark examples

Molecular dynamics

- Amber code: Atomistic



Amber 18 molecular dynamics

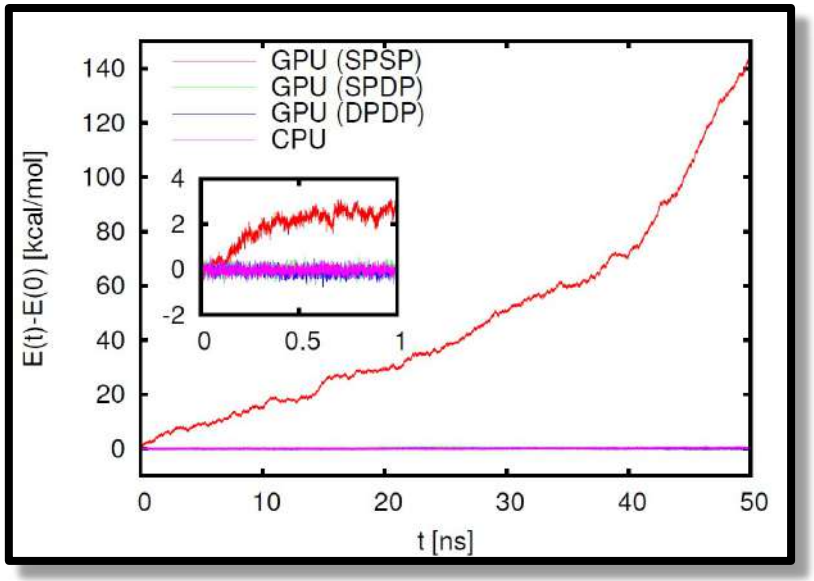
Götz, Williamson, Xu, Poole, Le Grand, Walker, *J Chem Theory Comput* 2012 (8) 1542.

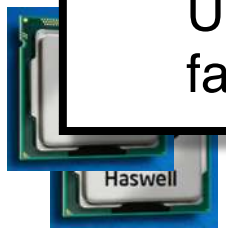
Le Grand, Götz, Walker, *Comput Phys Comm* 2013 (184) 374.

Salomon-Ferrer, Götz, Poole, Le Grand, Walker, *J Chem Theory Comput* 2012 (8) 1542.

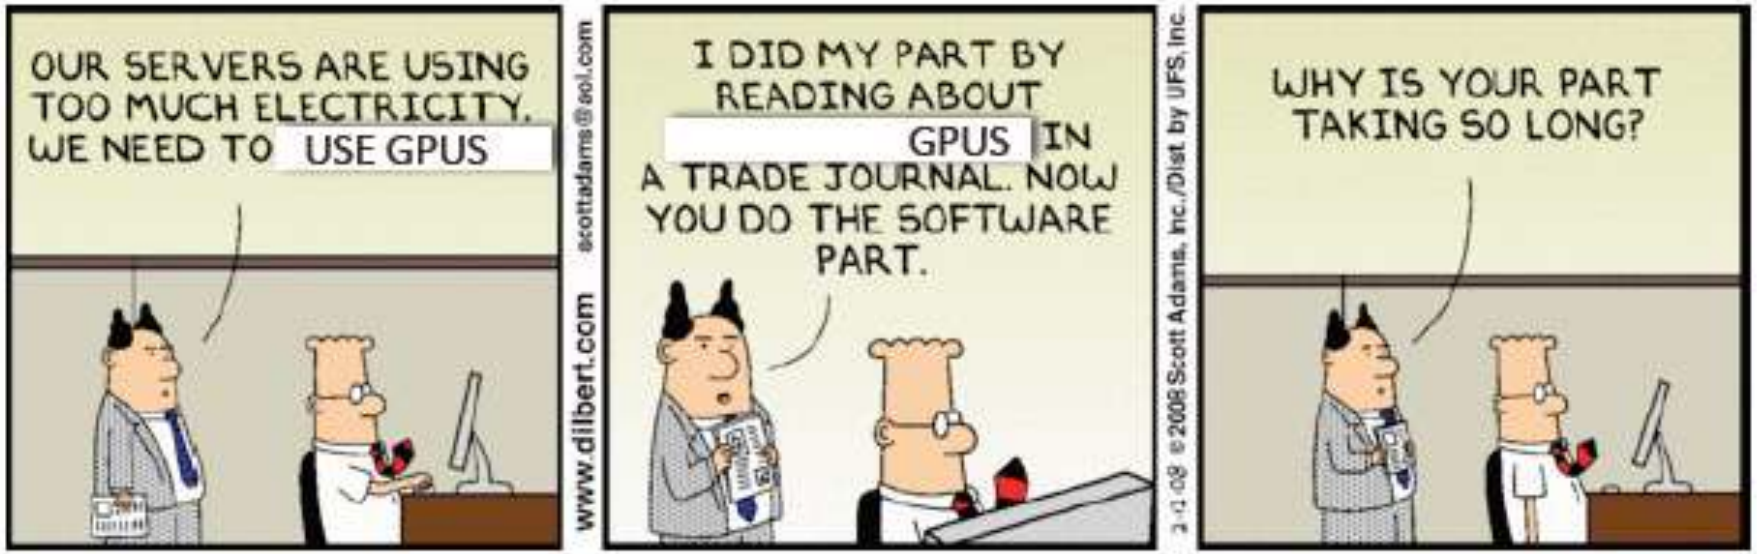
Precision matters

- ***SPSP***
  Only single precision
- ***SPDP***
  Single precision for calculation
  Double precision for accumulation
- ***DPDP***
  Full double precision
- ***SPFP***
  Single / Double / Fixed precision hybrid.
  Uses atomic ops for FP accumulation. Fully deterministic, faster and more precise than SPDP, minimal memory overhead

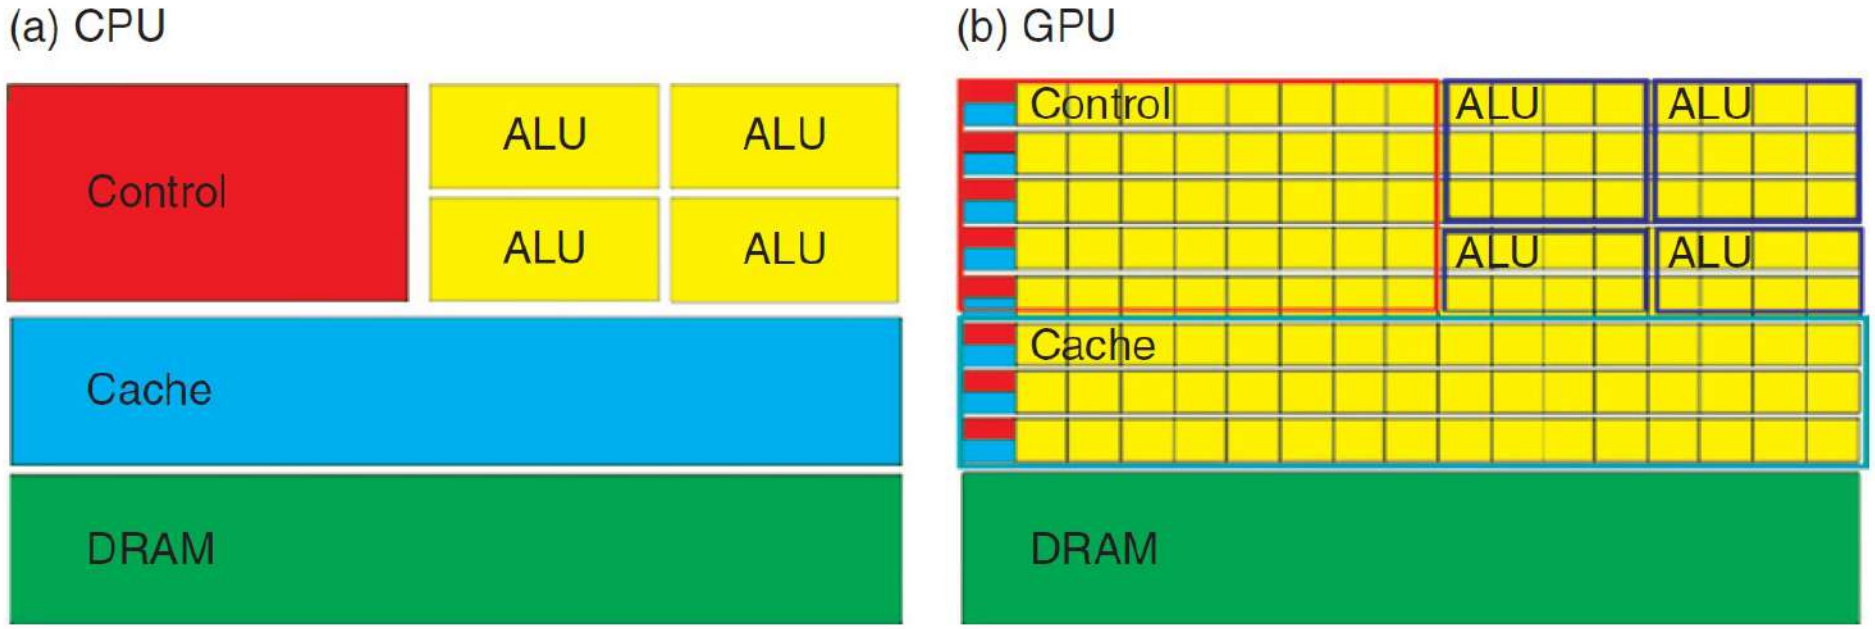




What's the catch?



GPU vs CPU architecture



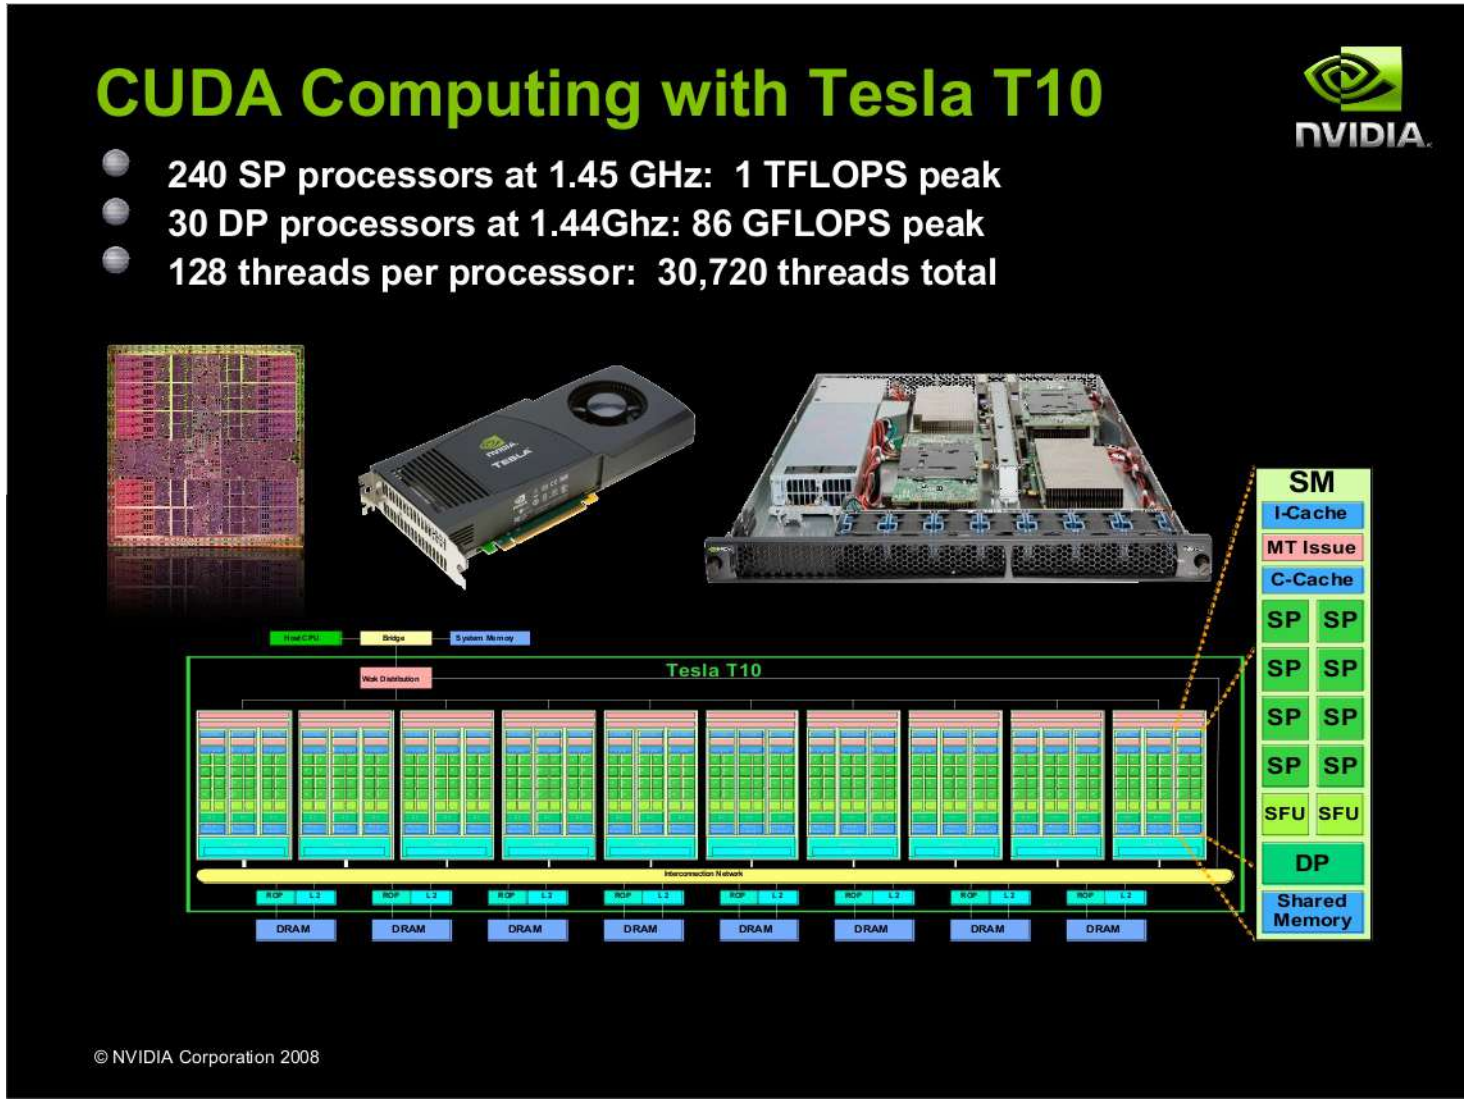
CPU

- Few processing cores with sophisticated hardware
- Multi-level caching
- Prefetching
- Branch prediction

GPU

- Thousands of simplistic compute cores (packaged into a few multiprocessors)
- Operate in lock-step
- Vectorized loads/stores to memory
- Need to manage memory hierarchy

GPU architecture



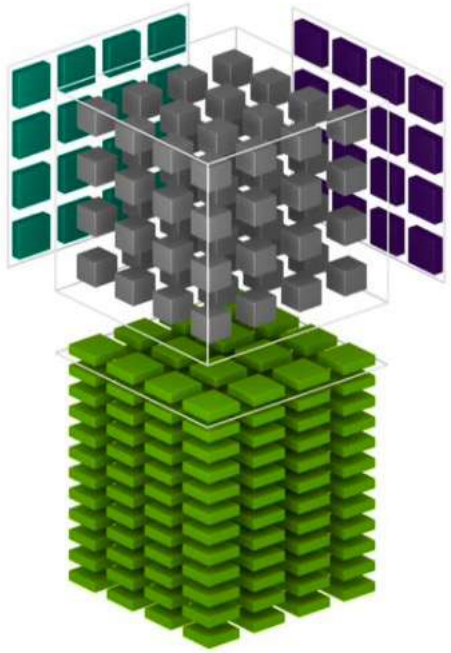
Nvidia GPU architecture in 2009

- Tesla T10, a server with early C1060 datacenter GPU
- Basic architecture is still the same

Multiprocessor

- SP compute cores
- DP compute core(s)
- Special function units
- Instruction cache
- Shared memory / data cache
- Handles many more threads than processing cores

Tensor cores



Accelerating MMA for FP64, TF32, Bfloat15, and FP16

- Tensor Cores are specialized hardware for deep learning that help accelerate matrix multiply and accumulate operations
- Nvidia Volta architecture introduced Tensor Cores with FP16 data types
- Nvidia Ampere GPUs introduce Tensore Core support for FP64, TF32, and Bfloat16 data types
- Deep learning operations that benefit from tensor cores are
  - Fully connected / linear / dense layers
  - Convolutional layers
  - Recurrent layers
- Tensor Cores are also used for mixed precision matrix operations (CUBLAS library)

Tensor core 4x4 matrix multiply and accumulate, Volta architecture

$$D = \underbrace{\begin{pmatrix} A_{0,0} & A_{0,1} & A_{0,2} & A_{0,3} \\ A_{1,0} & A_{1,1} & A_{1,2} & A_{1,3} \\ A_{2,0} & A_{2,1} & A_{2,2} & A_{2,3} \\ A_{3,0} & A_{3,1} & A_{3,2} & A_{3,3} \end{pmatrix}}_{\text{FP16 or FP32}} \underbrace{\begin{pmatrix} B_{0,0} & B_{0,1} & B_{0,2} & B_{0,3} \\ B_{1,0} & B_{1,1} & B_{1,2} & B_{1,3} \\ B_{2,0} & B_{2,1} & B_{2,2} & B_{2,3} \\ B_{3,0} & B_{3,1} & B_{3,2} & B_{3,3} \end{pmatrix}}_{\text{FP16}} + \underbrace{\begin{pmatrix} C_{0,0} & C_{0,1} & C_{0,2} & C_{0,3} \\ C_{1,0} & C_{1,1} & C_{1,2} & C_{1,3} \\ C_{2,0} & C_{2,1} & C_{2,2} & C_{2,3} \\ C_{3,0} & C_{3,1} & C_{3,2} & C_{3,3} \end{pmatrix}}_{\text{FP16 or FP32}}$$

Hardware complexities

Hardware characteristics change across GPU models and generations

- Single precision / double precision floating point performance
- Memory bandwidth
- Number of compute cores and multiprocessors
- Number of threads that the hardware can execute
- Number of registers and cache size
- Available GPU memory, device / shared

Memory hierarchy needs to be explicitly managed

- CPU memory, GPU global / shared / texture / constant memory
- Unified memory helps, but the memory hierarchy still exists

Different hardware vendors work in different ways

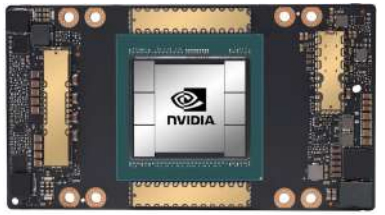
- Nvidia vs AMD

Hardware complexities

M40 – Nov 2015
- DP / SP = 1 / 3
- 12 or 24GB RAM

P100 – Q2 2016
- DP / SP = 1 / 2
- 16GB RAM

V100 – Q2 2017
- DP / SP = 1 / 2
- 16 or 32GB RAM



A100 – Q2 2020
- DP / SP = 1 / 2
- 40 or 80GB RAM

Data Center GPUs	C2050	K10	K20	K40	K80	M40	P100	V100	A100
#Multi Proc	14	8 (x2)	13	15	13 (x2)	24	56	80	108
SP Cores per MP	32	192	192	192	192	128	64	64	64
#Cores	448	1,536 (x2)	2,496	2,880	2,496 (x2)	3,072	3,584	5,120	6,912
Warp Size	32	32	32	32	32	32	32	32	32
DP Gflop/s	515	95 (x2)	1,170	1,680	1,455 (x2)	213	4,763	7,066	9,746

Nvidia GPU models

Nvidia compute capabilities determine features available on Nvidia GPUs

- E.g. double precision support since version 1.3

Hardware Version 7.0 (Volta V100)

- Titan-V
- V100

Hardware Version 6.1 (Pascal GP102/104)

•Titan-XP [aka Pascal Titan-X]
•GTX-1080TI / 1080 / 1070 / 1060
•Quadro P6000 / P5000
•P4 / P40

Hardware Version 6.0 (Pascal P100/DGX-1)

•Quadro GP100 (with optional NVLink)
•P100 12GB / P100 16GB / DGX-1

Hardware Version 8.0 (Ampere)

•RTX 3050, 3060, 3060Ti, 3070, 3080, 3090 (gaming)
•RTX A4000, A5000, A6000 (workstations)
•A10, A16, A30, A40, A100 (datacenter)

Hardware Version 7.5 (Turing)

•RTX 2060, 2070, 2080, 2080Ti (gaming)
•RTX A4000, A5000, A6000 (workstations)
•Quadro RTX 4000, 5000, 6000, 8000
•Tesla T4 (datacenter)

What this means for your program

Threads

- Never write code with any assumption for how many threads it will use.
- Use functions (CUDA calls in the case of Nvidia)
  to query the hardware configuration at runtime.
- Launch many more threads than processing cores.
  This helps hide memory access latency.

Data types

- Avoid using double precision where not specifically needed.

GPU programming languages

OpenCL

- Industry standard, works for Nvidia and AMD GPUs (and other devices)

CUDA

- Proprietary, works only for Nvidia GPUs
- De-facto standard for high-performance code

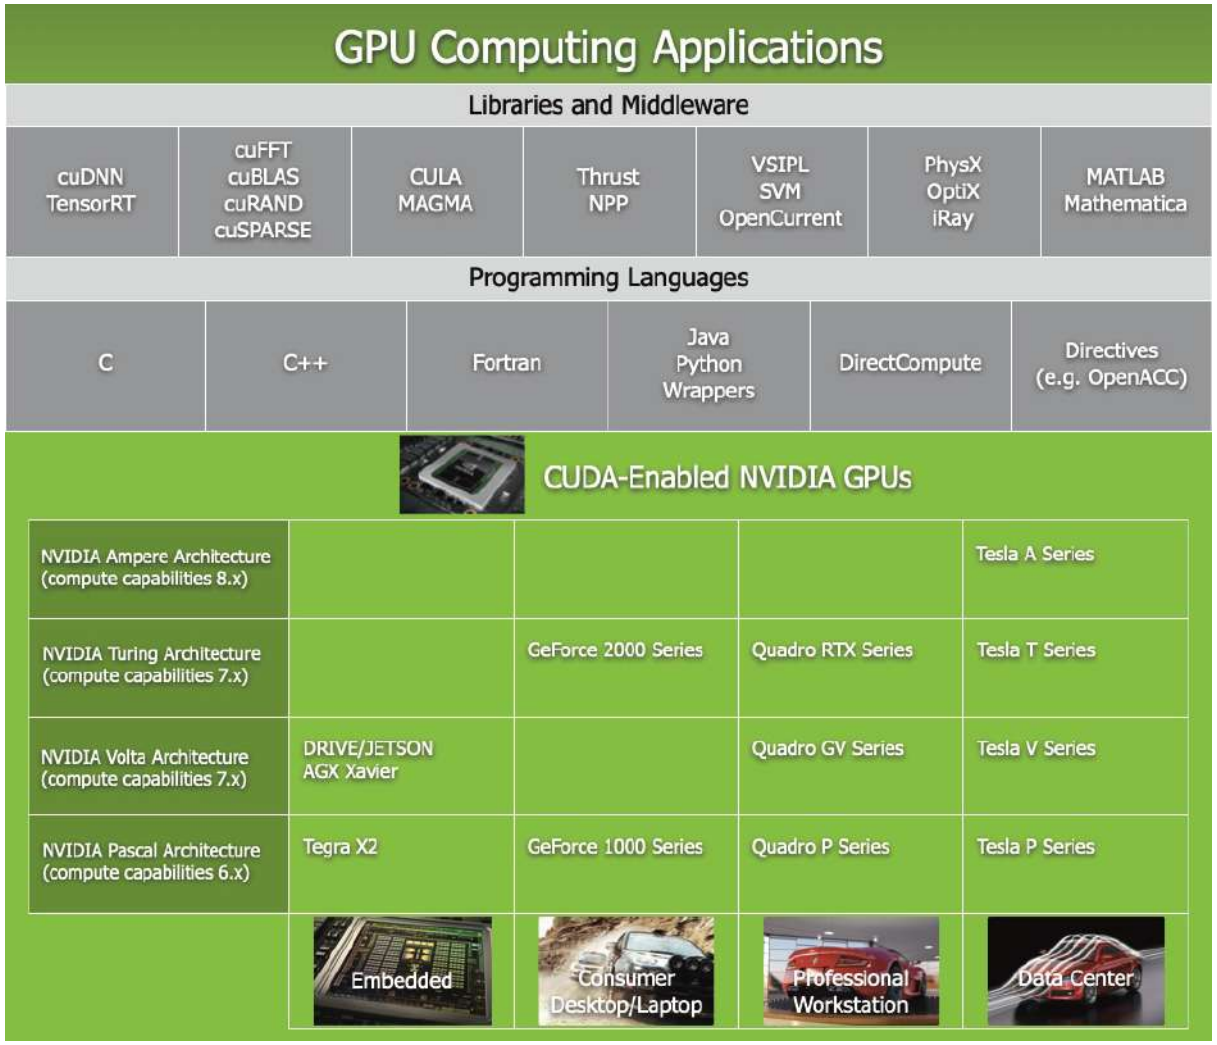
OpenACC

- Accelerator directives for Nvidia and AMD
- Works with C/C++ and Fortran

OpenMP

- Version 4.x includes accelerator and vectorization directives
- Not yet mature for GPUs

Nvidia GPU computing universe



Source: CUDA C programming guide https://docs.nvidia.com/cuda/cuda-c-programming-guide/index.html

Nvidia CUDA development tools

CUDA Toolkit/SDK (free)

- CUDA C compiler (nvcc)
- Libraries (cuBLAS, cuFFT, cuDNN, cuRAND, cuSPARSE, cuSOLVER, Thrust, CUDA Math lib)
- Debugging tools (CUDA-gdb, CUDA-memcheck)
- Profiling tools (nvprof, nvvp, Nsight Systems/Compute)
- Code samples
- https://developer.nvidia.com/cuda-zone
- https://nvidia.com/getcuda

Activate on Expanse GPU nodes

```
$> module purge
$> module reset
$> module load cuda
```

- Currently loads CUDA 11.0.2
- CUDA 10.2 also available

Nvidia CUDA development tools

Nvidia HPC SDK (free)

- Replaces the CUDA Toolkit
- Contains most of CUDA Toolkit including CUDA compiler nvcc, libraries, debuggers, profiler
- Nvidia C/C++, Fortran compiler (nvfortran, nvc, nvc++) (formerly PGI compilers)
- https://developer.nvidia.com/hpc-sdk

Activate on Expanse GPU nodes

```
$> module purge
$> module reset
$> module load nvhpc
```

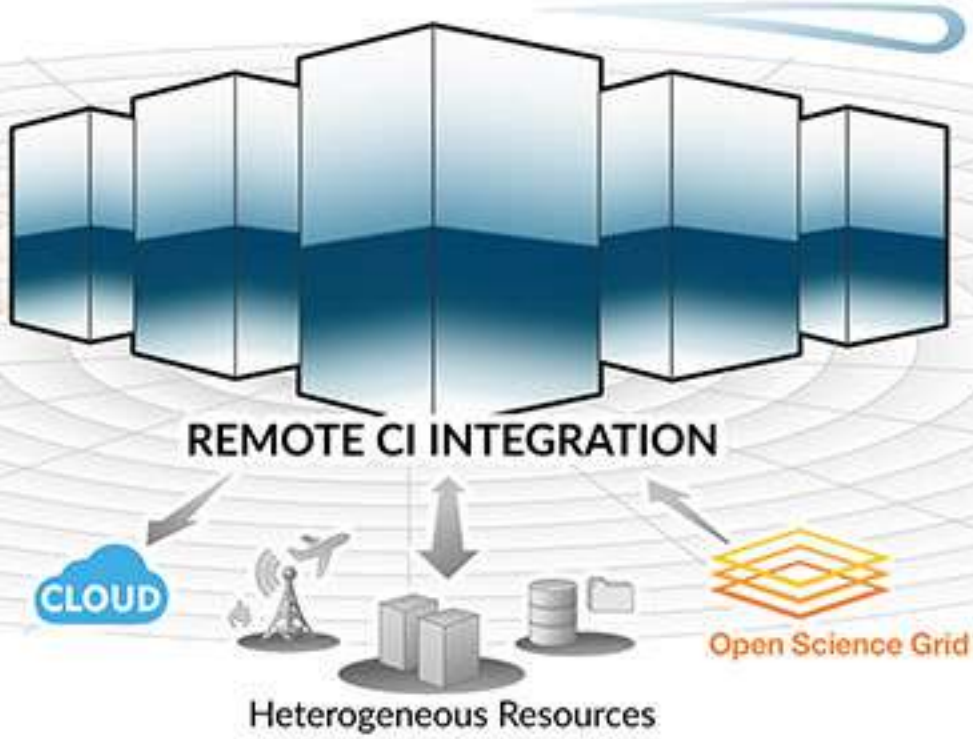
SDSC Expanse GPU nodes

SDSC Expanse

Launched in Fall 2020

HPC RESOURCE
13 Scalable Compute Units
728 Standard Compute Nodes
52 GPU Nodes: 208 GPUs
4 Large Memory Nodes

DATA CENTRIC ARCHITECTURE
12PB Perf. Storage: 140GB/s, 200k IOPS
Fast I/O Node-Local NVMe Storage
7PB Ceph Object Storage
High-Performance R&E Networking



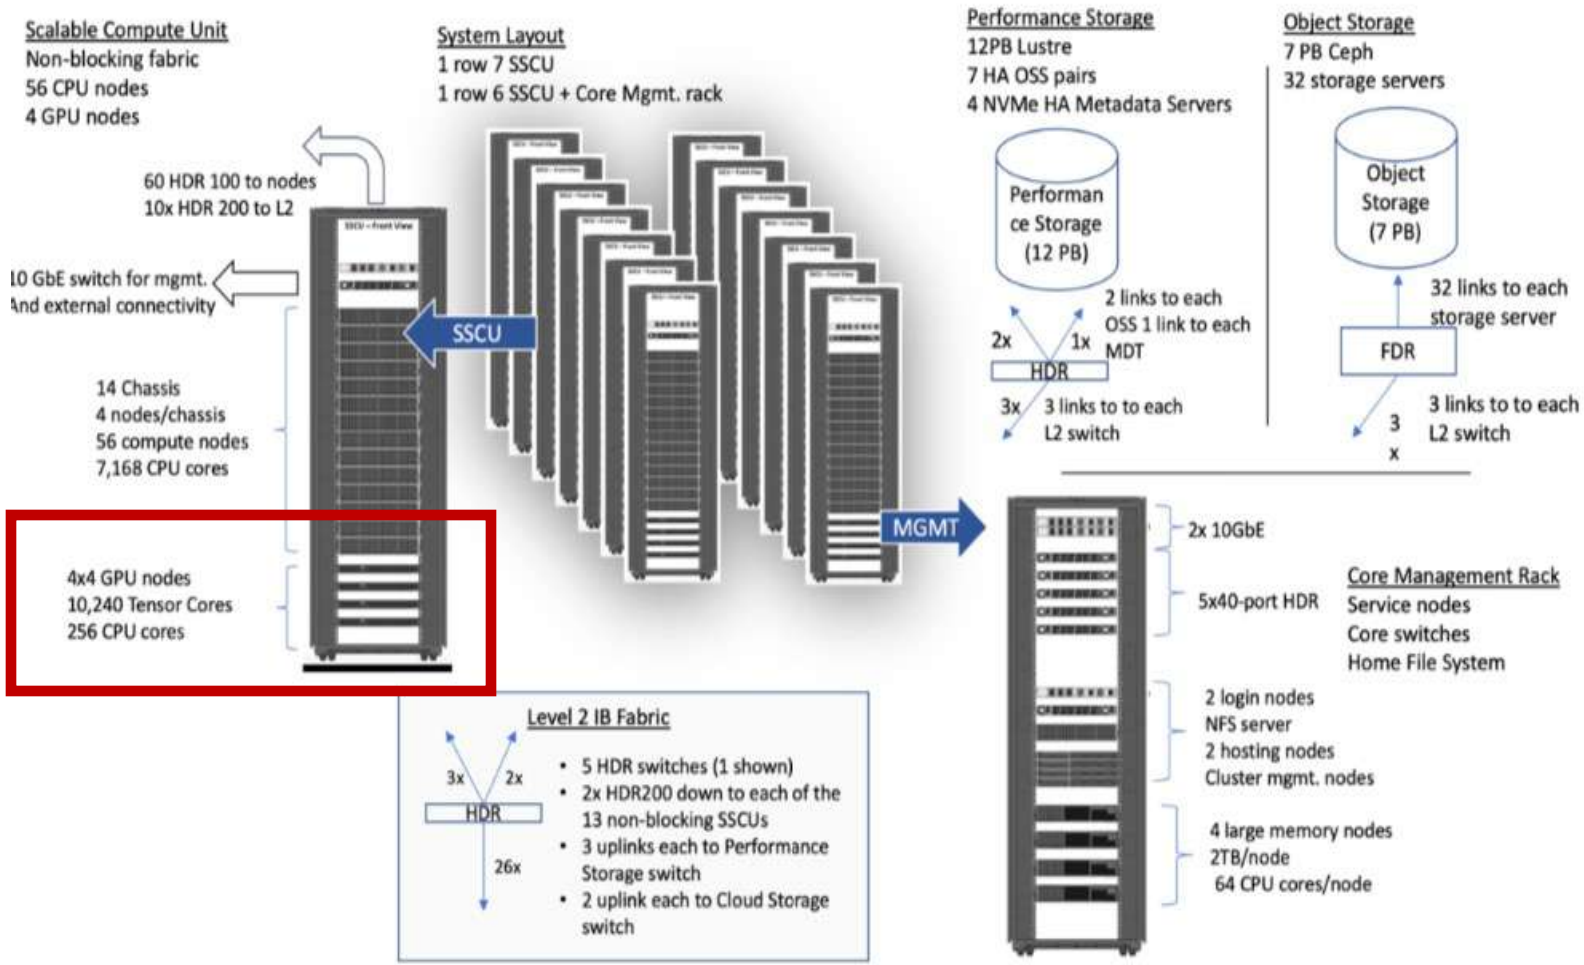
LONG-TAIL SCIENCE
Multi-Messenger Astronomy
Genomics
Earth Science
Social Science

INNOVATIVE OPERATIONS
Composable Systems
High-Throughput Computing
Science Gateways
Interactive Computing
Containerized Computing
Cloud Bursting

Expanse Heterogeneous Architecture

System Summary

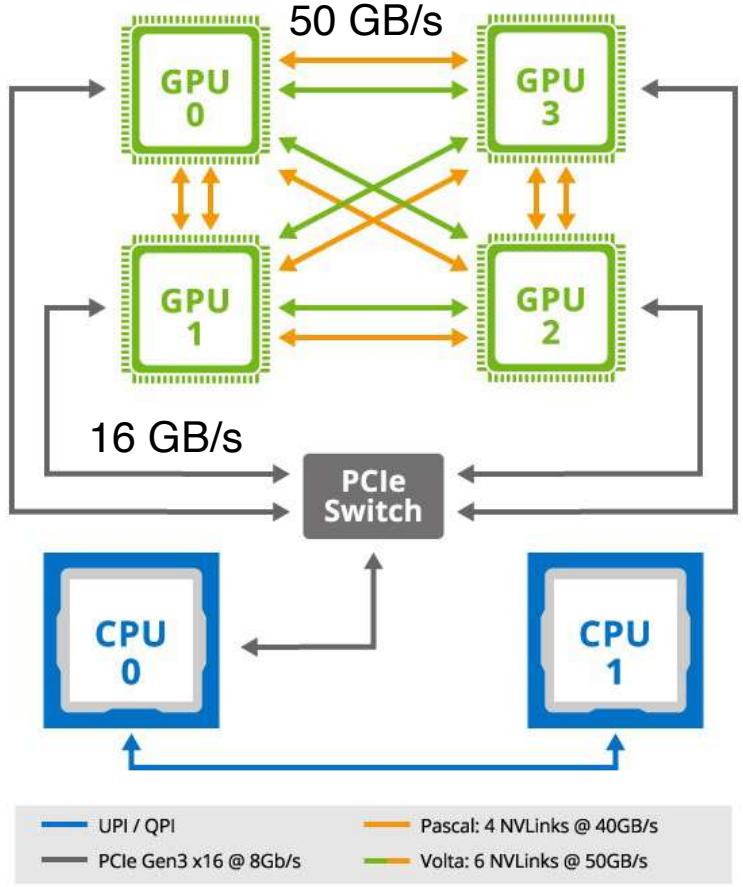
- 13 SDSC Scalable Compute Units (SSCU)
- 728 Standard Compute Nodes
- 93,184 Compute Cores
- 200 TB DDR4 Memory
- 52x 4-way GPU Nodes w/NVLINK
- **208 V100 GPUs**
- 4x 2TB Large Memory Nodes
- HDR 100 non-blocking Fabric
- 12 PB Lustre High Performance Storage
- 7 PB Ceph Object Storage
- 1.2 PB on-node NVMe
- Dell EMC PowerEdge
- Direct Liquid Cooled

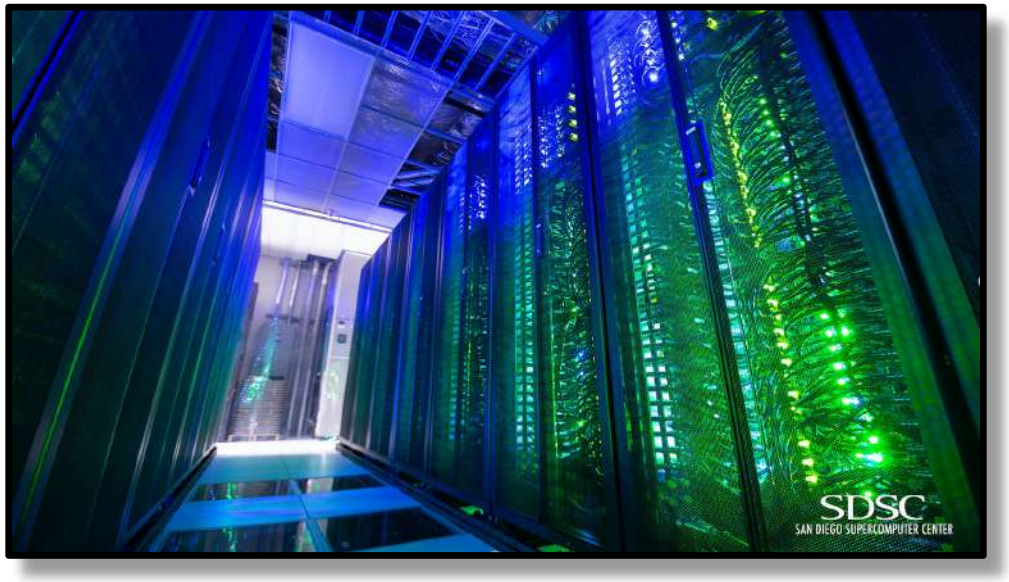


SDSC Expanse GPU nodes with Nvidia V100 SXM2

52 GPU nodes

- 2 x 20-core Intel Xeon Gold 6248 (Cascade Lake) CPUs
- 384 GB RAM (131 GB/s)
- 4 x Nvidia V100 SXM2 GPUs
- 32 GB HBM2 RAM per GPU (897 GB/s)
- 1.6 TB NVMe/node





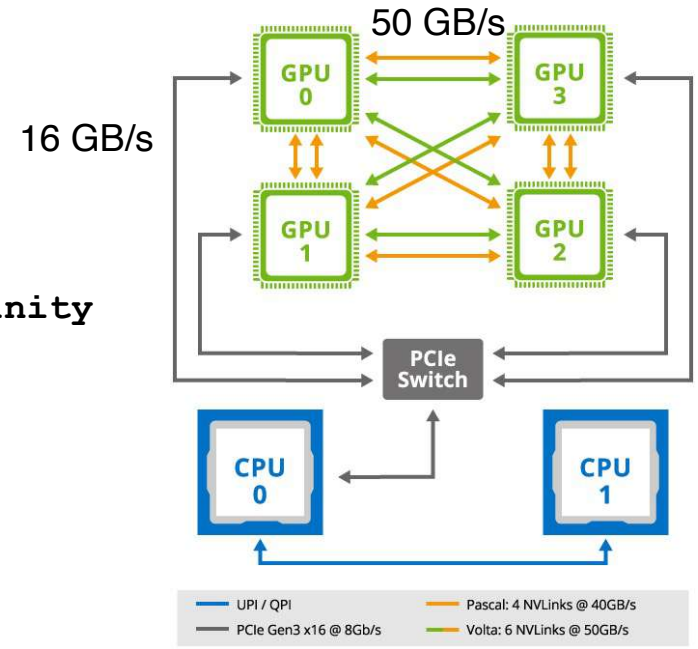
User guide:
https://www.sdsc.edu/support/user_guides/expanse.html

SDSC Expanse GPU nodes with Nvidia V100 SXM2

Node topology

Output of `nvidia-smi topo -m`

	GPU0	GPU1	GPU2	GPU3	mlx5_0	CPU Affinity	NUMA Affinity
GPU0	X	NV2	NV2	NV2	NODE	0,2,4,6,8,10	0
GPU1	NV2	X	NV2	NV2	NODE	0,2,4,6,8,10	0
GPU2	NV2	NV2	X	NV2	SYS	1,3,5,7,9,11	1
GPU3	NV2	NV2	NV2	X	SYS	1,3,5,7,9,11	1
mlx5_0	NODE	NODE	SYS	SYS	X		

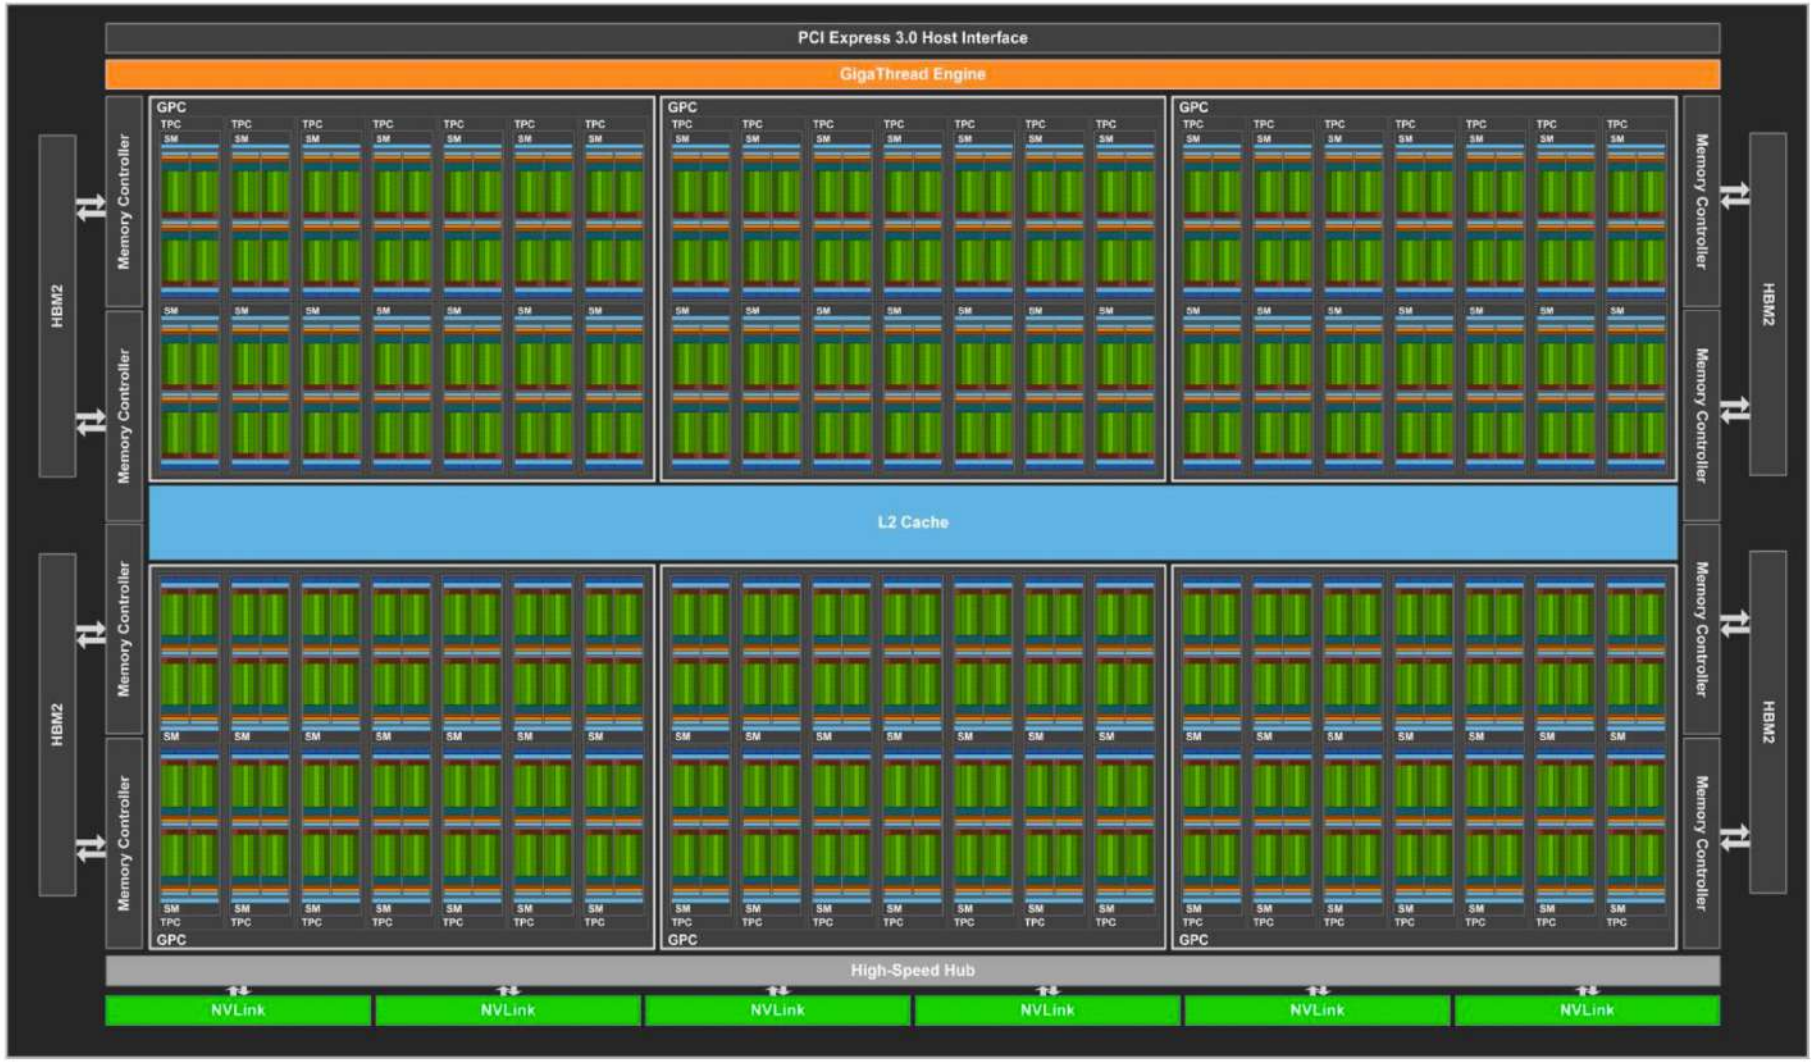


Legend:

```
  X    = Self
  SYS  = Connection traversing PCIe as well as the SMP interconnect between NUMA nodes (e.g., QPI/UPI)
  NODE = Connection traversing PCIe as well as the interconnect between PCIe Host Bridges within a NUMA node
  PHB  = Connection traversing PCIe as well as a PCIe Host Bridge (typically the CPU)
  PXB  = Connection traversing multiple PCIe bridges (without traversing the PCIe Host Bridge)
  PIX  = Connection traversing at most a single PCIe bridge
  NV#  = Connection traversing a bonded set of # NVLinks
```

SDSC Expanse – V100 SXM2 GPUs

SDSC Expanse – V100 SXM2 GPUs



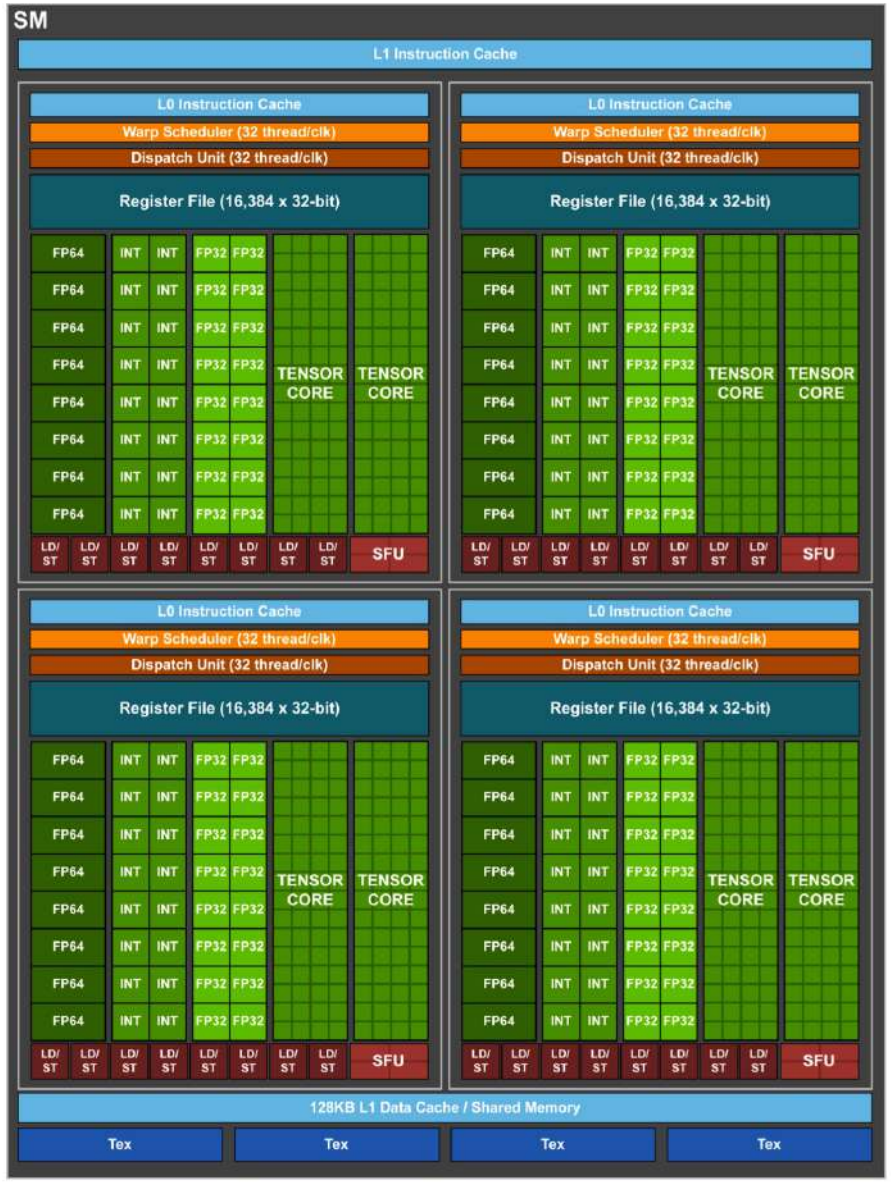
SDSC Expanse – V100 SXM2 GPUs

Each GPU

- 32 GB HBM2 RAM (897 GB/s)
- 80 SMs (Streaming Multiprocessors)
- 64 FP32 cores / SM (5120 total)
- 32 FP64 cores / SM (2560 total)
- 8 Tensor cores / SM (640 total)
- 300 Watt TDP

Peak performance

- 7.8 FP64 TFLOPs
- 15.7 FP32 TFLOPs
- 31.3 FP16 TFLOPs
- 125 Tensor TFLOPs



SDSC Expanse login

Login

Use the following commands to adjust your environment:

'module avail'             - show available modules
'module add <module>'      - adds a module to your environment for this session
'module initadd <module>' - configure module to be loaded at every login

--------------------------------------------------------------------------------
Last login: Tue Apr 27 01:58:53 2021 from 136.26.112.138
[agoetz@login01 ~]$
```

SDSC Expanse GPU node access

- The GPU nodes can be accessed via two different partitions
  "gpu" (entire nodes with 4 GPUs) and "gpu-shared" (individual GPUs).

```
#SBATCH --partition=gpu
```

or

```
#SBATCH --partition=gpu-shared
```

- In addition to the partition name (required), the number of GPUs must be specified.

```
#SBATCH --gpus=n
```

- For example, to obtain access to a single GPU for 30 minutes in an interactive session

```
srun --partition=gpu-shared --nodes=1 --gpus=1 --ntasks-per-node=1 --cpus-per-task=10 \
     --mem=80G --time=00:30:00 --wait=0 --pty /bin/bash

srun: job 2210010 queued and waiting for resources
srun: job 2210010 has been allocated resources
[agoetz@exp-8-59 ~]$
```

SDSC Expanse GPU node access

- Note to make requests proportional to the number of available resources.
  - 4 x V100 GPUs
  - 40 CPU cores
  - 374 GB RAM
- Do not request more than 10 CPU cores and 93GB RAM per GPU, otherwise you will be charged for proportionally more time.

SDSC Expanse GPU nodes

- For this course we have an alias to get access to a single GPU on the shared queue for 2 hours:

```
get-gpu
```

Please try to get access to an Expanse GPU node now

- Purge, then load GPU related modules

```
module purge
module reset
module load sdsc
```

```
# Either Load CUDA Toolkit and PGI compiler
module load cuda
module load pgi

# Or load Nvidia HPC SDK
module load nvhpc

# Note: CUDA samples work only with
#       CUDA Toolkit 10.2
```

SDSC Expanse GPU nodes

- Interactive access to GPU nodes

```
[agoetz@login01 ~] srun --partition=gpu-shared --nodes=1 --gpus=1 \
                        --ntasks-per-node=1 --cpus-per-task=10 --mem=90GB \
                        --time=02:00:00 --pty --wait=0 /bin/bash
```

- Check available GPUs using Nvidia system management interface

```
[agoetz@exp-8-59 ~]$ nvidia-smi

SDSC Expanse GPU nodes

- Check Nvidia CUDA C compiler

```
[agoetz@exp-8-59 ~]$ nvcc --version
nvcc: NVIDIA (R) Cuda compiler driver
Copyright (c) 2005-2020 NVIDIA Corporation
Built on Wed_Jul_22_19:09:09_PDT_2020
Cuda compilation tools, release 11.0, V11.0.221
Build cuda_11.0_bu.TC445_37.28845127_0
```

- Check PGI C compiler

```
[agoetz@exp-8-59 ~]$ pgcc --version

pgcc (aka nvc) 20.9-0 LLVM 64-bit target on x86-64 Linux -tp skylake
PGI Compilers and Tools
Copyright (c) 2020, NVIDIA CORPORATION.  All rights reserved.
```

SDSC Expanse GPU nodes

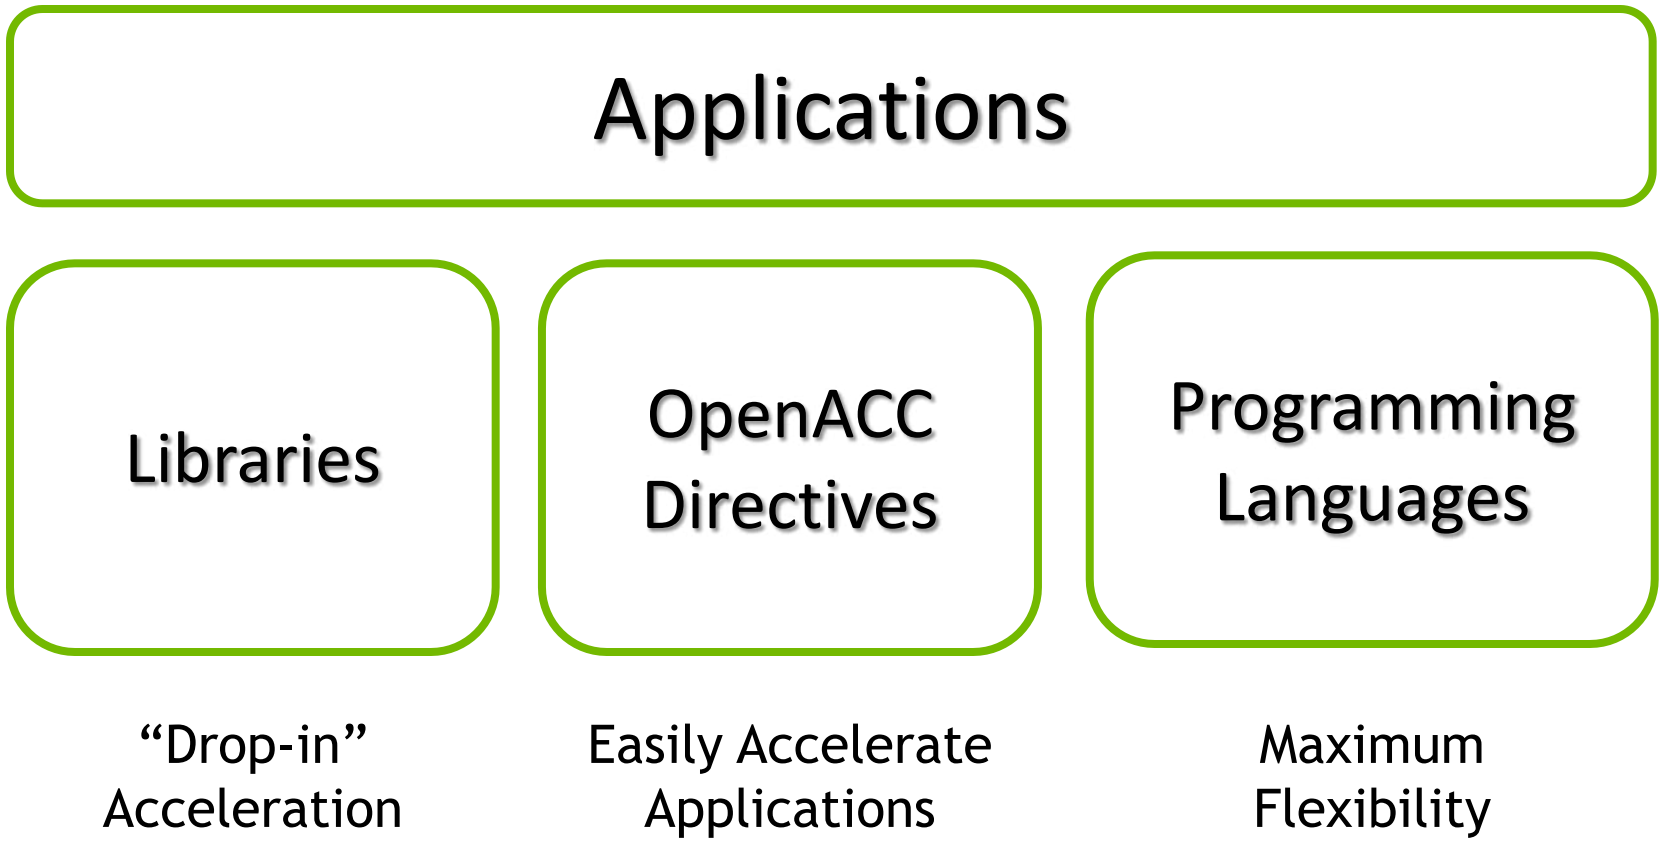
- There should be no jobs running on the GPU assigned to you.

```
...
+-----------------------------------------------------------------------------+
| Processes:                                                                  |
|  GPU   GI   CI        PID   Type   Process name                  GPU Memory |
|        ID   ID                                                   Usage      |
|=============================================================================|
|  No running processes found                                                 |
+-----------------------------------------------------------------------------+
```

- The nodes of the shared GPU queue are configured for the CUDA runtime to use only the requested number of GPUs.
- Check environment variable **`CUDA_VISIBLE_DEVICES`** and you should see the GPUs enumerated (e.g. `0,1` if you had requested 2 GPUs).

Using GPU accelerated libraries

3 ways to use GPUs



GPU accelerated libraries

Ease of use

- GPU acceleration without in-depth knowledge of GPU programming

“Drop-in”

- Many GPU accelerated libraries follow standard APIs
- Minimal code changes required

Quality

- High-quality implementations of functions encountered in a broad range of applications

Performance

- Libraries are tuned by experts

=> Use if you can – (do not write your own matrix multiplication)

GPU accelerated libraries

See https://developer.nvidia.com/gpu-accelerated-libraries

Deep Learning Libraries

cuDNN

GPU-accelerated library of primitives for deep neural networks

GPU-accelerated neural network inference library for building deep learning applications

Advanced GPU-accelerated video inference library

Signal, Image and Video Libraries

cuFFT

GPU-accelerated library for Fast Fourier Transforms

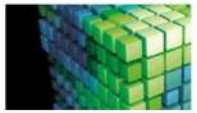
NVIDIA Performance Primitives

GPU-accelerated library for image and signal processing

NVIDIA Codec SDK

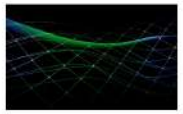
High-performance APIs and tools for hardware accelerated video encode and decode

Linear Algebra and Math Libraries



cuBLAS

GPU-accelerated standard BLAS library



CUDA Math Library

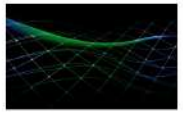
GPU-accelerated standard mathematical function library

cuSPARSE

GPU-accelerated BLAS for sparse matrices

cuRAND

GPU-accelerated random number generation (RNG)



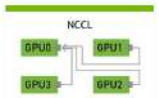
cuSOLVER

Dense and sparse direct solvers for Computer Vision, CFD, Computational Chemistry, and Linear Optimization applications

AmgX

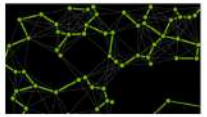
GPU accelerated linear solvers for simulations and implicit unstructured methods

Parallel Algorithm Libraries



NCCL

Collective Communications Library for scaling apps across multiple GPUs and nodes



nvGRAPH

GPU-accelerated library for graph analytics

Thrust

GPU-accelerated library of parallel algorithms and data structures

Partner Libraries

… and several others

GPU accelerated libraries

3 steps to using libraries

- Step 1: Substitute library calls with equivalent CUDA library calls

  `saxpy ( … )` → `cublasSaxpy ( … )`

- Step 2: Manage data locality

  - with CUDA: `cudaMalloc(), cudaMemcpy(), etc.`
  - with CUBLAS: `cublasSetVector(), cublasGetVector()` `etc.`

- Step 3: Rebuild and link the CUDA-accelerated library

```
nvcc myobj.o –l cublas
```

CUBLAS library example

```
int N = 1 << 20;
```

saxpy =
single precision
a times **x** **p**lus **y**

$y = a * x + y$

```
// Perform SAXPY on 1M elements: y[]=a*x[]+y[]
saxpy(N, 2.0, d_x, 1, d_y, 1);
```

CUBLAS library example

```
int N = 1 << 20;
```

```
// Perform SAXPY on 1M elements: d_y[]=a*d_x[]+d_y[]
cublasSaxpy(handle, N, 2.0, d_x, 1, d_y, 1);
```

Add “cublas” prefix and use device variables

CUBLAS library example

```
int N = 1 << 20;
cublasCreate(&handle);
```

```
// Perform SAXPY on 1M elements: d_y[]=a*d_x[]+d_y[]
cublasSaxpy(handle, N, 2.0, d_x, 1, d_y, 1);
```

```
cublasDestroy(handle);
```

CUBLAS library example

```
int N = 1 << 20;
cublasCreate(&handle);
cudaMalloc((void**)&d_x, N*sizeof(float));
cudaMalloc((void**)&d_y, N*sizeof(float));
```

Allocate device vectors

```
// Perform SAXPY on 1M elements: d_y[]=a*d_x[]+d_y[]
cublasSaxpy(handle, N, 2.0, d_x, 1, d_y, 1);
```

```
cudaFree(d_x);
cudaFree(d_y);
cublasDestroy(handle);
```

Deallocate device vectors

CUBLAS library example

```
int N = 1 << 20;
cublasCreate(&handle);
cudaMalloc((void**)&d_x, N*sizeof(float));
cudaMalloc((void**)&d_y, N*sizeof(float));

cublasSetVector(N, sizeof(x[0]), x, 1, d_x, 1);
cublasSetVector(N, sizeof(y[0]), y, 1, d_y, 1);

// Perform SAXPY on 1M elements: d_y[]=a*d_x[]+d_y[]
cublasSaxpy(N, 2.0, d_x, 1, d_y, 1);

cublasGetVector(N, sizeof(y[0]), d_y, 1, y, 1);

cublasFree(d_x);
cublasFree(d_y);
cublasDestroy(handle);
```

Transfer data to GPU

Read data back from GPU

CUBLAS library example

```
int N = 1 << 20;
cublasCreate(&handle);
cudaMalloc((void**)&d_x, N*sizeof(float));
cudaMalloc((void**)&d_y, N*sizeof(float));

cublasSetVector(N, sizeof(x[0]), x, 1, d_x, 1);
cublasSetVector(N, sizeof(y[0]), y, 1, d_y, 1);

// Perform SAXPY on 1M elements: d_y[]=a*d_x[]+d_y[]
cublasSaxpy(N, 2.0, d_x, 1, d_y, 1);

cublasGetVector(N, sizeof(y[0]), d_y, 1, y, 1);

cublasFree(d_x);
cublasFree(d_y);
cublasDestroy(handle);
```

CUDA C Basics

Nvidia CUDA

See https://developer.nvidia.com/cuda-zone

CUDA C

- Solution to run C seamlessly on GPUs (Nvidia only)
- De-facto standard for high-performance code on Nvidia GPUs
- Nvidia proprietary
- Modest extensions but major rewriting of code

CUDA Fortran

- Supports CUDA extensions in Fortran, developed by Portland Group Inc (PGI)
- Available in the Nvidia Fortran compiler (formerly PGI Fortran Compiler)
- PGI is now part of Nvidia

Recommended Reading

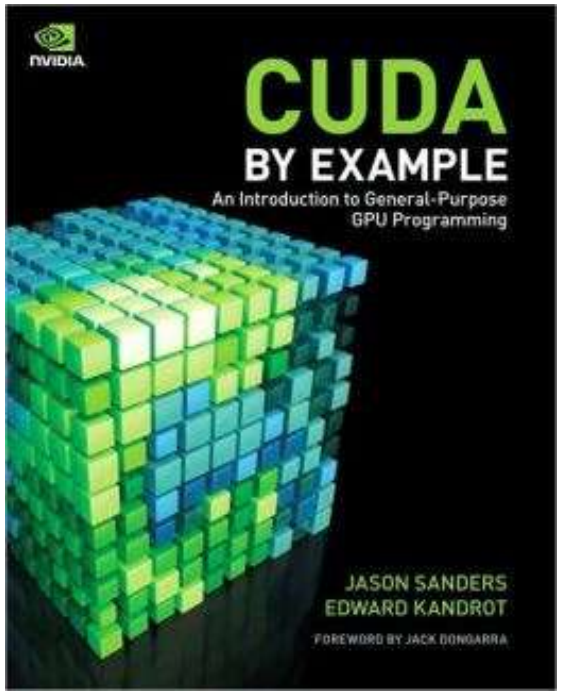
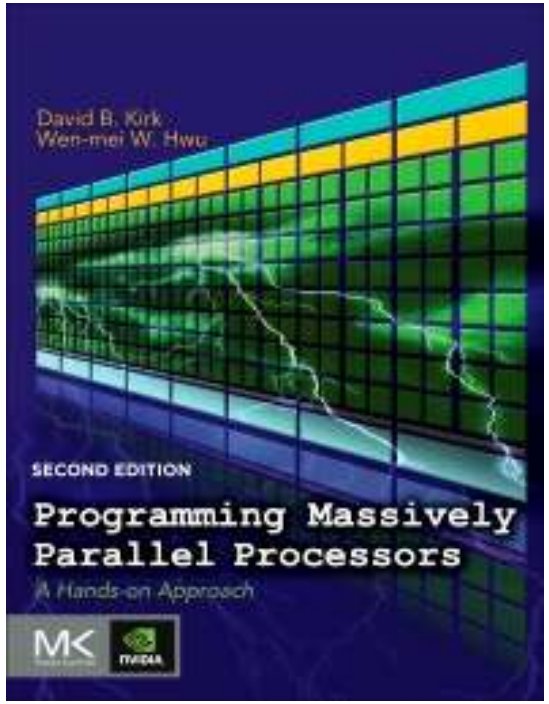
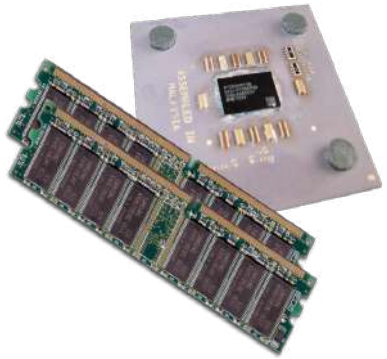
Good books to get started





Heterogeneous Computing

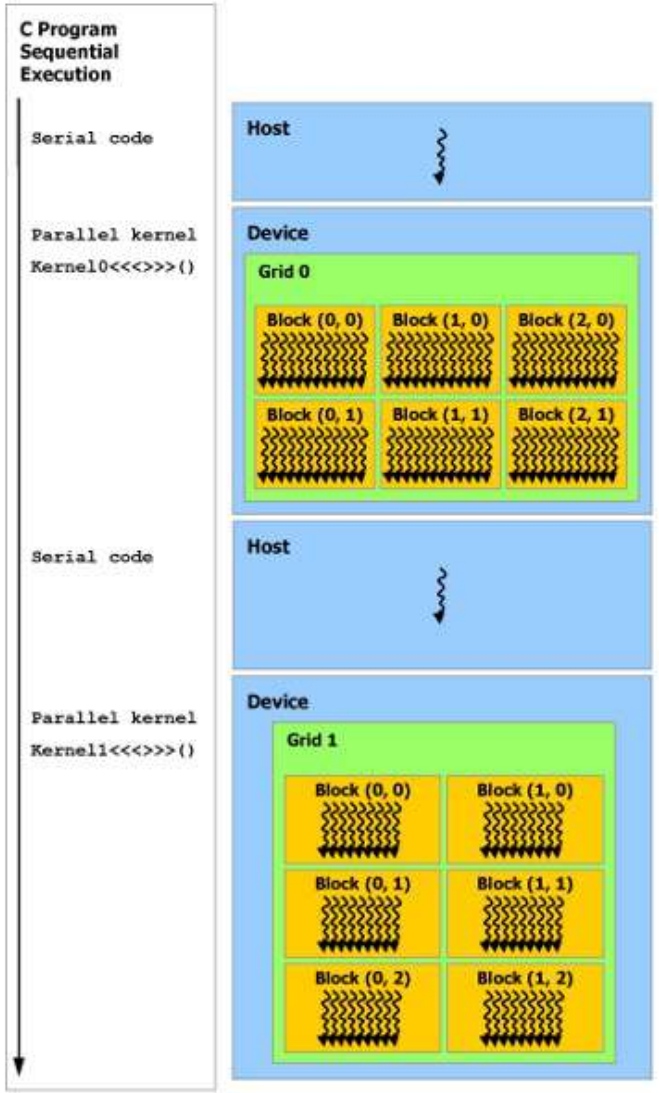
- Host The CPU and its memory
- Device The GPU and its memory
- Device code is launched from Host code



Host

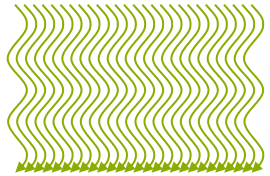
Device

Heterogeneous Computing



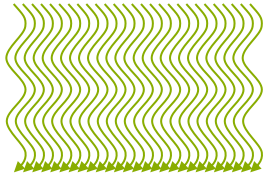
serial code

parallel code

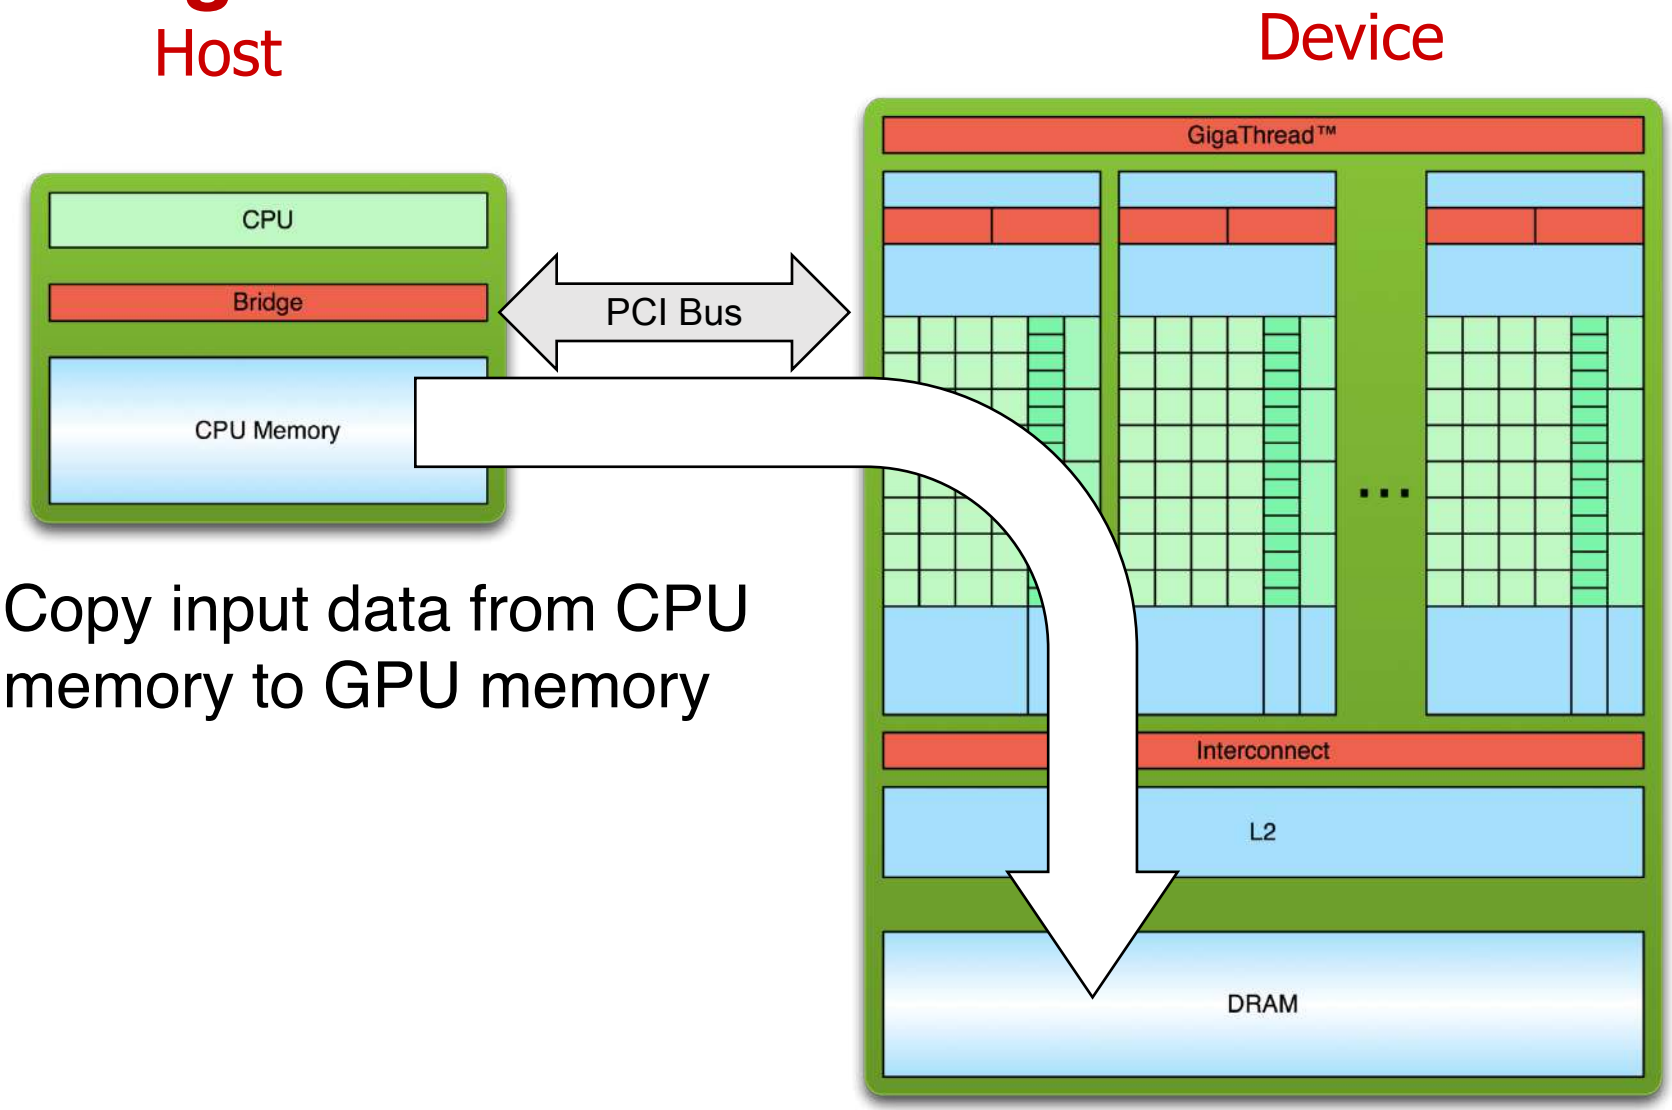


serial code

parallel code

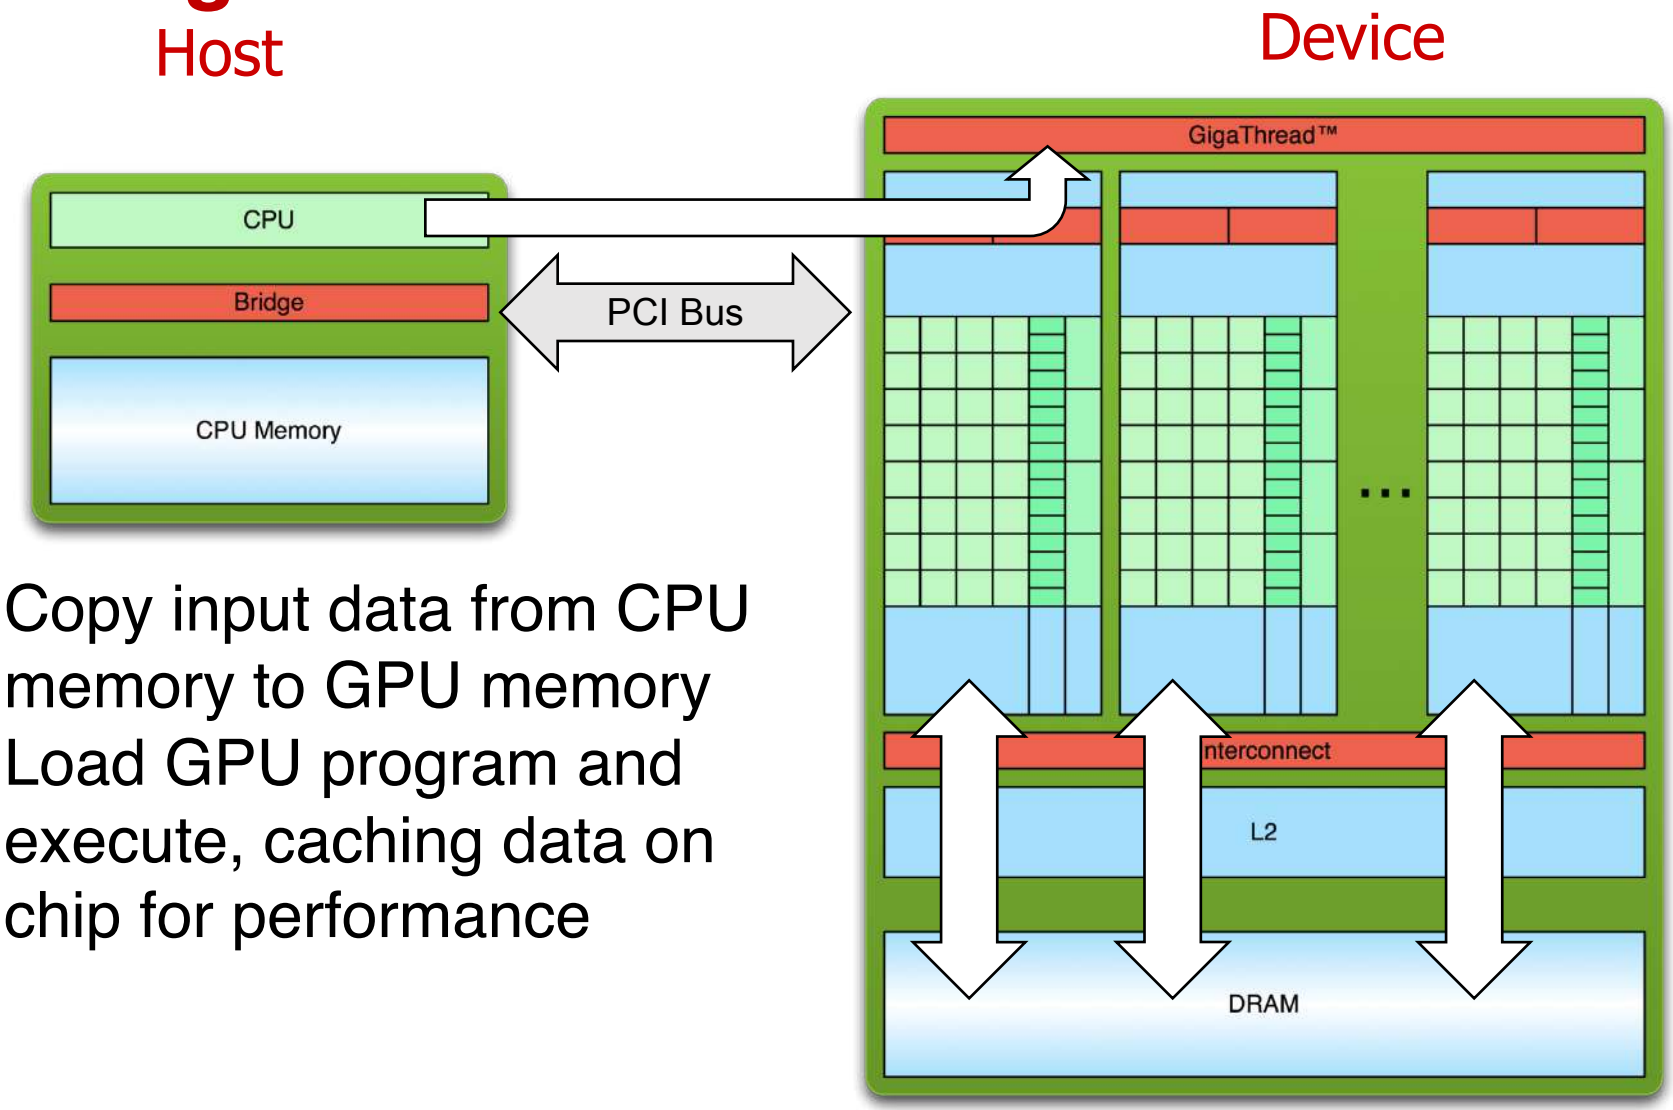


Processing Flow



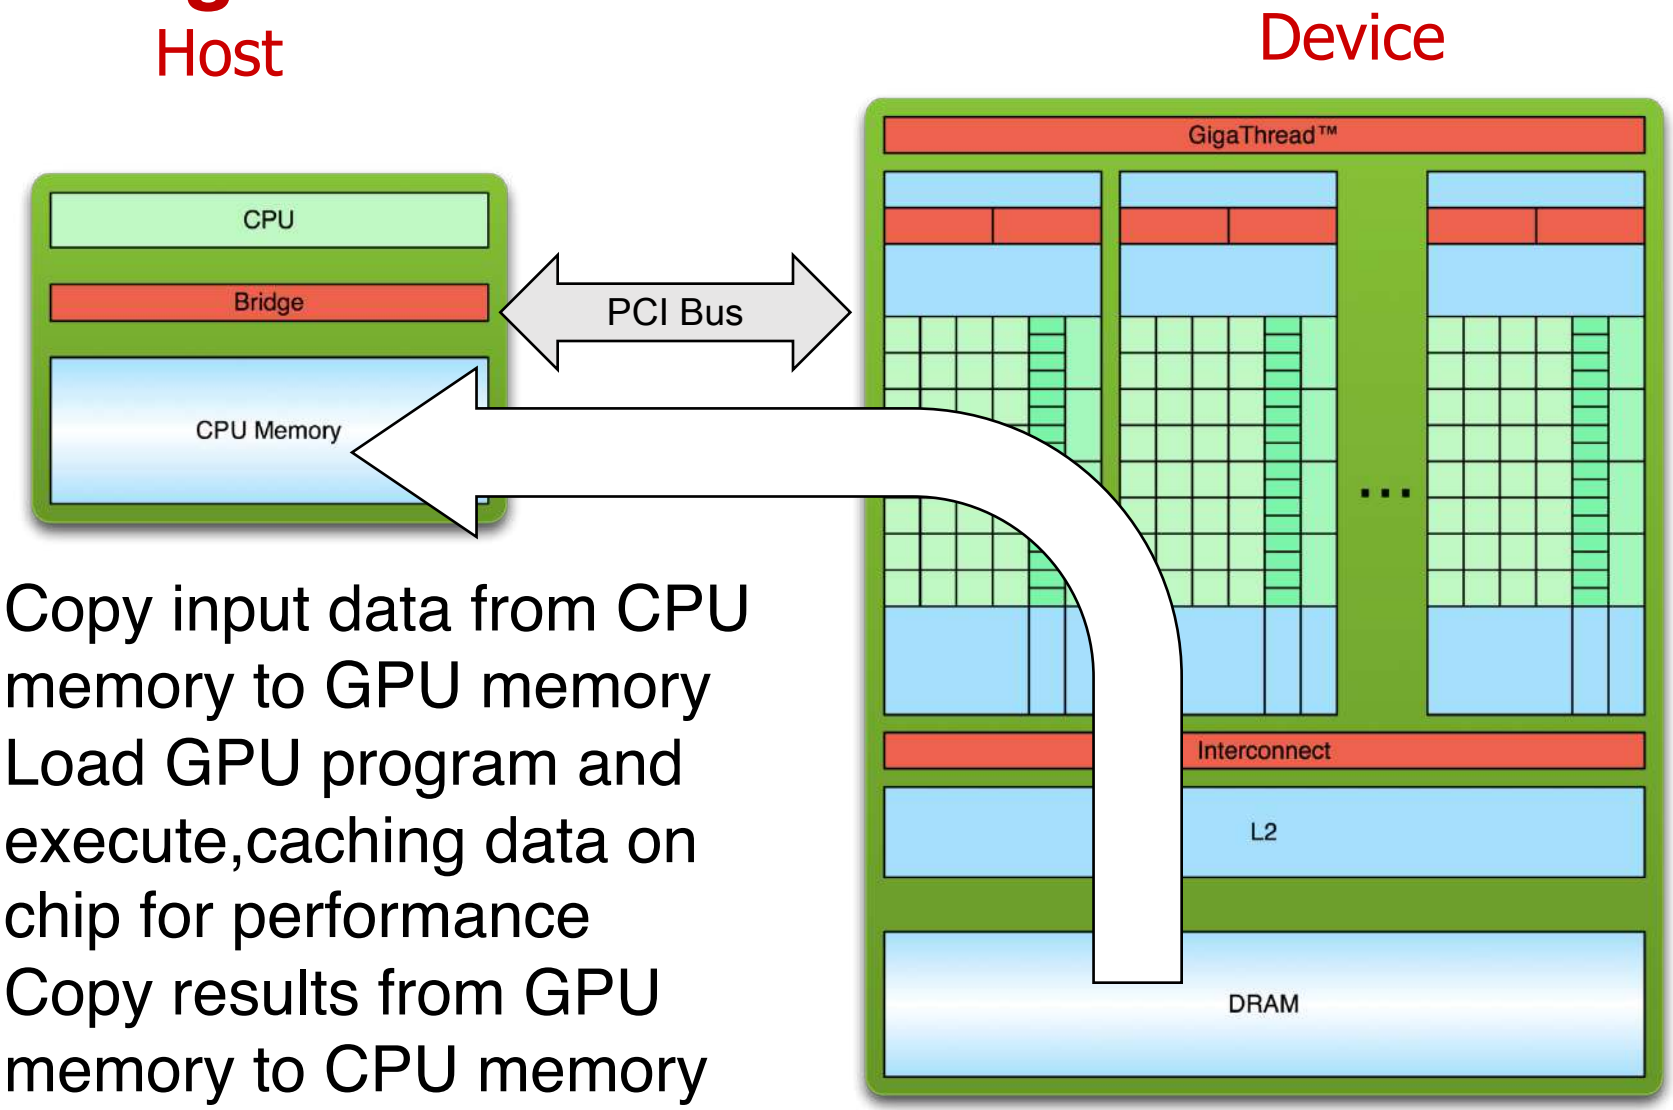
1. Copy input data from CPU memory to GPU memory

Processing Flow



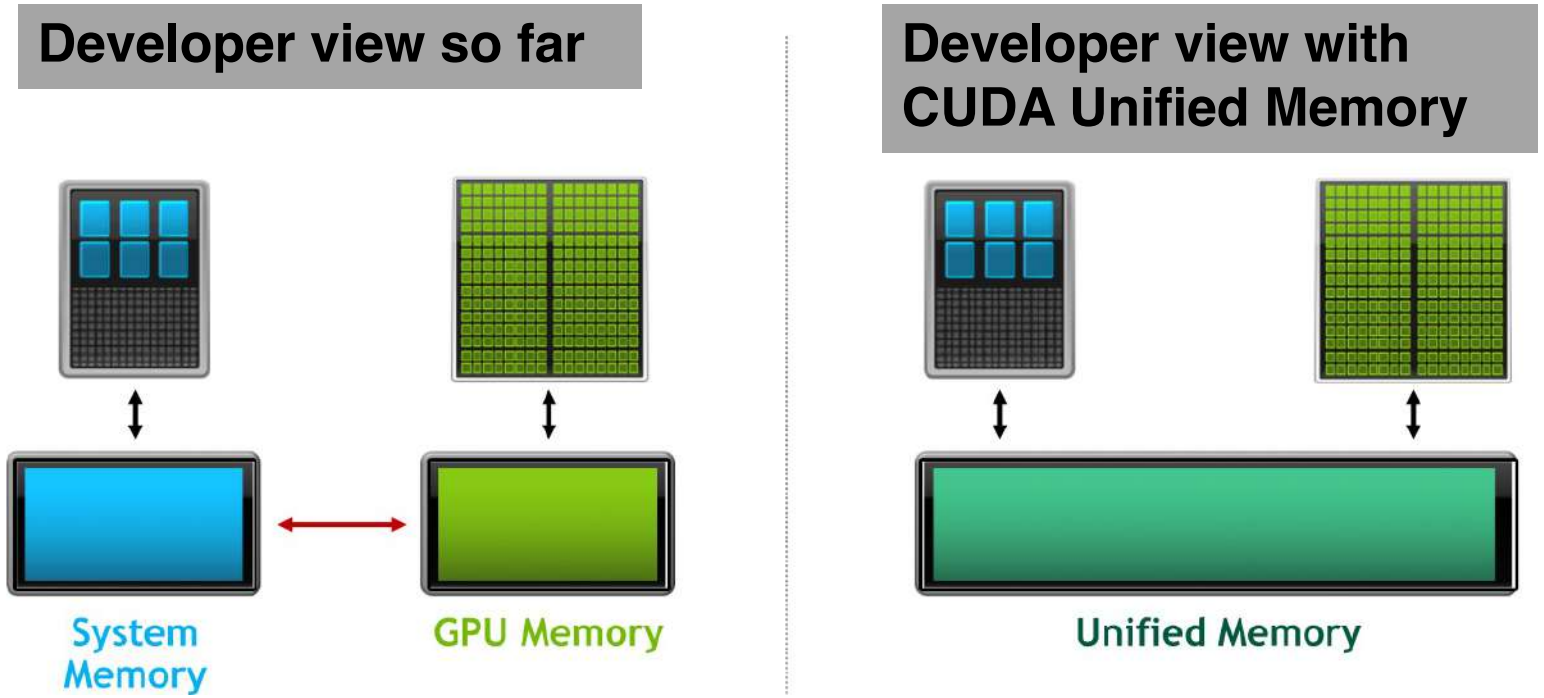
1. Copy input data from CPU memory to GPU memory
2. Load GPU program and execute, caching data on chip for performance

Processing Flow



1. Copy input data from CPU memory to GPU memory
2. Load GPU program and execute,caching data on chip for performance
3. Copy results from GPU memory to CPU memory

Unified memory



- Pool of managed memory that is shared between host and device
- Primarily productivity feature
- Memory copies still happen under the hood
- Available since CUDA 6 on Kepler architecture
- Page fault mechanisms supported since Pascal architecture

Hello World!

Standard C code

```
int main(void) {
        printf("Hello World!\n");
        return 0;
}
```

- Standard C code that runs on the host
- Compile with NVIDIA CUDA compiler (nvcc)
  - nvcc separates into host and device code
  - Host code is compiled by host compiler

```
$> nvcc hello_world_cpu.cu
$> ./a.out
Hello World!
```

Standard C code with CUDA extensions

```
__global__ void my_kernel(void){
}

int main(void) {
        my_kernel<<<16,32>>>();
        printf("Hello World!\n");
        return 0;
}
```

- Contains code that is executed on the device (though doing nothing)
- Two new syntactic elements…

Hello World!

- CUDA C keyword `__global__` indicates a function that
  - runs on the device (and must return **`void`**)
  - can be called from the host code

```
__global__ void my_kernel(void){
}
```

- **`nvcc`** separates source code into host and device components
  - device functions processed by **`nvcc`**
  - host functions processed by standard C compiler, e.g. **`gcc`**

Hello World!

- Triple angle brackets mark a call from host code to device code
  - Called kernel launch
  - Parameters in brackets are kernel launch configuration (explained later)

```
__global__ void my_kernel(void){
}

int main(void) {
        my_kernel<<<16,32>>>();
        printf("Hello World!\n");
        return 0;
}
```

  - The kernel **`my_kernel()`** does nothing …
  - Let's look at writing code to be executed on the GPU

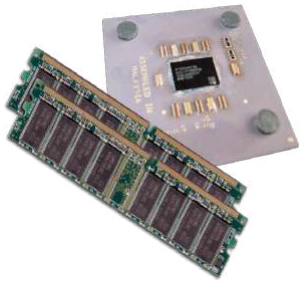
Addition on the device

```
__global__ void add(int *a, int *b, int *c){
        *c = *a + *b;
}
```

- Remember: `__global__` is a CUDA C keyword, thus
  - **`add()`** will execute on the device
  - **`add()`** will be called from the host
- Thus **`a`**, **`b`** and **`c`** must point to device memory

Memory management

- Host and device memory are separate
  - Host pointers point to CPU memory
    - Can be passed to/from device code
    - Cannot be dereferenced in device code!
  - Device pointers point to GPU memory
    - Can be passed to/from host code
    - Cannot be dereferenced in host code!
- CUDA API handles device memory
  - **`cudaMalloc(), cudaFree(), cudaMemcpy()`**
  - equivalent to C **`malloc(), free(), memcpy()`**



Addition on the device

```
__global__ void add(int *a, int *b, int *c){
        *c = *a + *b;
}
```

- How do we reserve memory on the device?
- How do we transfer data from the host to the device?
- This happens in the host C code that launches the kernel. Let's see how this works…

Addition on the device

```
int main(void){
    int h_a, h_b, h_c;     // host copies
    int *d_a, *d_b, *d_c; // device copies
    int size = sizeof(int);

    // Allocate memory on device
    cudaMalloc((void **)&d_a, size);
    cudaMalloc((void **)&d_b, size);
    cudaMalloc((void **)&d_c, size);

    // Setup input values
    h_a = 5;
    h_b = 7;

    // Copy input data to device
    cudaMemcpy(d_a, &h_a, size,
                    cudaMemcpyHostToDevice);
    cudaMemcpy(d_b, &h_b, size,
                    cudaMemcpyHostToDevice);

    // Launch add() kernel
    add<<<1,1>>>(d_a, d_b, d_c);

    // Copy results back to host
    cudaMemcpy(&h_c, d_c, size,
                     cudaMemcpyDeviceToHost);

    // Deallocate memory
    cudaFree(d_a); cudaFree(d_b); cudaFree(d_c);

    printf("%d + %d = %d", h_a, h_b, h_c);
    return 0;
}
```

Basic CUDA workflow

- Allocate memory on the device
- Copy input data to the device
- Launch CUDA kernel on the device
- Copy results back to the host
- Deallocate memory on the device

Let's move on to parallel computing on the GPU using CUDA

Parallelization with CUDA

- GPU computing is about massive parallelism
  - How do we run code in parallel using CUDA?
- Instead of executing the kernel add() once, we execute it N times in parallel
- The central idea defining GPU computing:
  - Kernels look like serial programs
  - Write programs as if they run on a single thread
  - The GPU will run that program on many threads

Parallelization with CUDA

- Executing **`add()`** N times

```
add<<<1,1>>>();  // launch 1 copy
```

```
add<<<N,1>>>();  // launch N copies
```

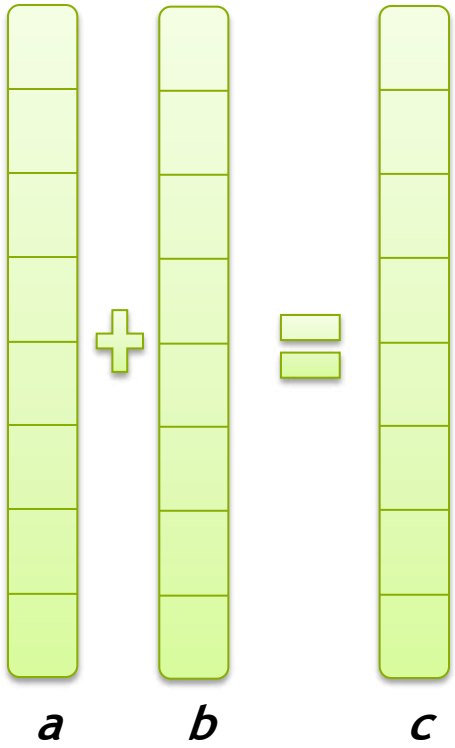
- The GPU is good at
  - efficiently launching lots of threads
  - running lots of threads in parallel
    (many more than processors on the device)
- But why launch N identical copies?

Vector addition

- CPU code (serial) uses a loop

```
#define N 512
void vadd_cpu(int *a, int *b, int *c){
        int i;
        for (i=0; i<N; i++){
                c[i] = a[i] + b[i];
        }
}
```

- The GPU does this in parallel by running N copies of the **`add()`** kernel, each copy working on a different vector element



Parallel vector addition (1)

- Parallelized **`add()`** kernel

```
__global__ void add(int *a, int *b, int *c){
        int tid = blockIdx.x;
        c[tid] = a[tid] + b[tid];
}
```

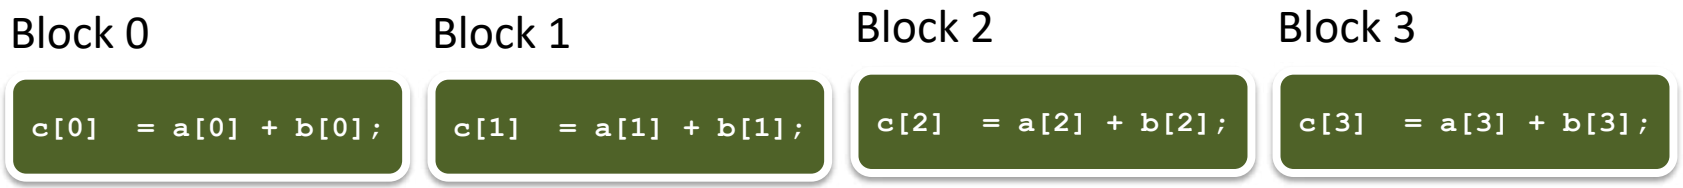
- Each parallel invocation of **`add()`** is called a block. The set of blocks is called a grid
- Each kernel instance knows its block index
- By using its index, each block operates on different data

Parallel vector addition (1)

- We launch N blocks of the **`add()`** kernel

```
// launch N copies
add<<<N,1>>>(d_a, d_b, d_c);
```

- Kernel call needs to be consistent with kernel implementation
- On the device, each block can execute in parallel, depending on the number and type of available multiprocessors



Parallel vector addition (1)

```
// CUDA kernel for vector addition
__global__ void add(int *a, int *b, int *c){
        int tid = blockIdx.x;
        c[tid] = a[tid] + b[tid];
}

#define N 512
int main(void){
        int h_a[N], h_b[N], h_c[N];  // host copies
        int *d_a, *d_b, *d_c;        // device copies
        int size = N * sizeof(int);

        // Allocate memory on device
        cudaMalloc((void **)&d_a, size);
        cudaMalloc((void **)&d_b, size);
        cudaMalloc((void **)&d_c, size);
```

Parallel vector addition (1)

```
    // Setup input values
    get_input_vectors(h_a, h_b);

    // Copy input data to device
    cudaMemcpy(d_a, h_a, size, cudaMemcpyHostToDevice);
    cudaMemcpy(d_b, h_b, size, cudaMemcpyHostToDevice);

    // Launch N blocks of the add() kernel
    add<<<N,1>>>(d_a, d_b, d_c);

    // Copy results back to host
    cudaMemcpy(h_c, d_c, size, cudaMemcpyDeviceToHost);

    // Deallocate memory
    cudaFree(d_a); cudaFree(d_b); cudaFree(d_c);

    return 0;
}
```

Review

- Distinguish host and device code
  - host = CPU
  - device = GPU
- CUDA keyword `__global__` declares functions as device code
  - execute on device
  - called from host
- Parameters can be passed from host code to device function

- Basic device memory management
  - `cudaMalloc()`
  - `cudaMemcpy()`
  - `cudaFree()`
- Kernels are launched by CPU and execute in parallel
  - Launch N blocks (copies) of add() with

    ```
    add<<<N,1>>>(…);
    ```

  - Use `blockIdx.x` to access block index

CUDA blocks and threads

- Blocks contain threads executing in parallel
- Parallelized **`add()`** kernel using threads

```
__global__ void add(int *a, int *b, int *c){
        int tid = threadIdx.x;
        c[tid] = a[tid] + b[tid];
}
```

- Each kernel instance knows its index
- Parallel kernel call

```
// launch N copies
add<<<1,N>>>(d_a, d_b, d_c);
```

CUDA blocks and threads

- Blocks contain threads executing in parallel
- Parallelized **`add()`** kernel using threads

```
__global__ void add(int *a, int *b, int *c){
        int tid = threadIdx.x;
        c[tid] = a[tid] + b[tid];
}
```

- Each kernel instance knows its index
- Parallel kernel call

```
// launch N copies
add<<<1,N>>>(d_a, d_b, d_c);
```

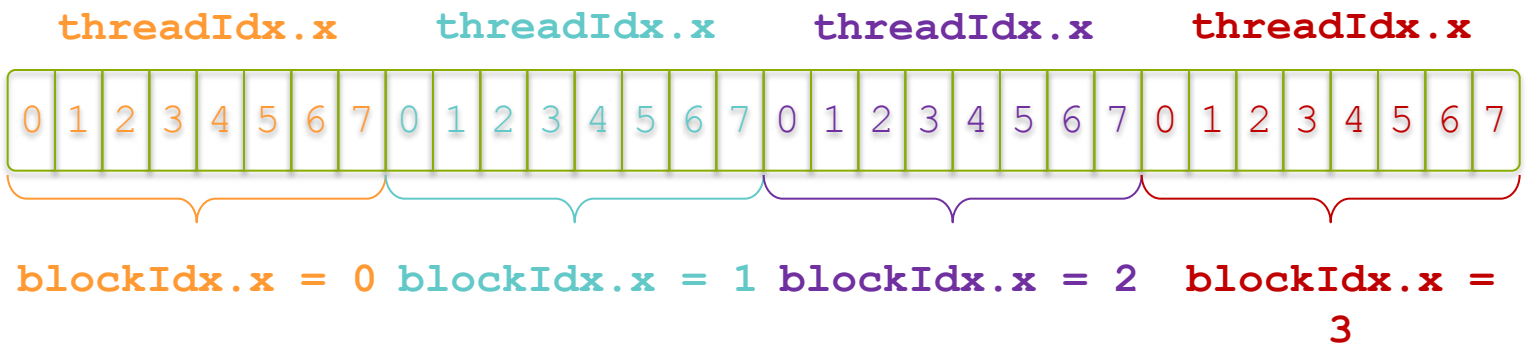
- We can combine blocks and threads
  - need to take care with indexing

- CUDA supports 3D blocks and threads (more later)
- Number of allowed threads per block and concurrent blocks is limited by hardware (up to 2048 threads per block on current GPUs)
- Threads and blocks map to the underlying hardware
- All threads in a block are guaranteed to execute on the same streaming multiprocessor (SM), thus sharing resources
- Threads within a block can communicate and synchronize
- **Note:** Thread block size should be a multiple of warp size (32) for performance reasons since kernels issue instructions in warps

Indexing with blocks and threads

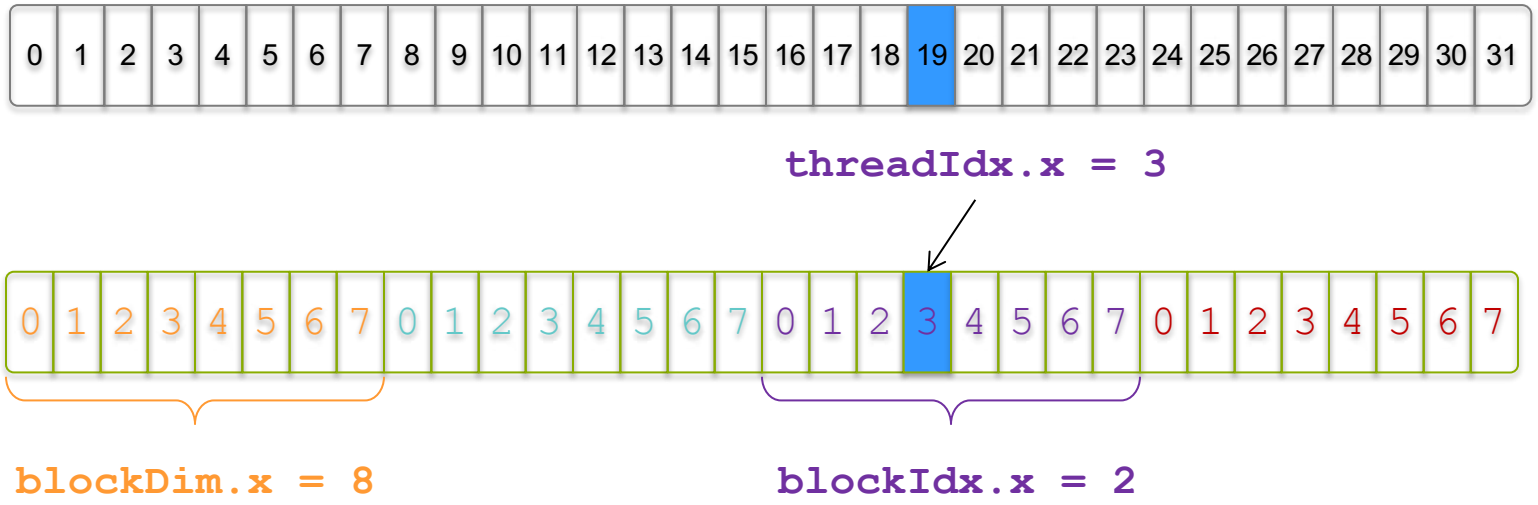
Example to compute offset into an array

- 1 element per thread
- 8 threads per block



- Built-in variable **`blockDim.x`** contains the number of threads per block
  - this makes it possible to calculate a unique index (e.g. offset into an array) for each kernel

Indexing with blocks and threads



- Calculate a unique index (Example: blue field above has index 19)

```
int tid = threadIdx.x + blockIdx.x * blockDim.x
        = 3           + 2           * 8
        = 19
```

Parallel vector addition (2)

- Parallelized **`add()`** using blocks and threads

```
__global__ void add(int *a, int *b, int *c){
        int tid = threadIdx.x + blockDim.x * blockIdx.x;
        c[tid] = a[tid] + b[tid];
}
```

- Corresponding kernel call

```
// launch N/TPB copies with
// TPB threads per block
add<<<N/TPB,TPB>>>(d_a, d_b, d_c);
```

Handling arbitrary vector sizes (1)

- Problem size **N** is typically **not** a multiple of our chosen **blockDim.x**
- Launch a sufficient number of kernels

```
// launch at least N/TBP copies with
// TPB threads per block
add<<<(N+TBP-1)/TPB,TPB>>>(d_a, d_b, d_c, N);
```

- Ensure to stay within array boundaries

```
__global__ void add(int *a, int *b, int *c, int n){
        int tid = threadIdx.x + blockDim.x * blockIdx.x;
        if (tid < n)
             c[tid] = a[tid] + b[tid];
}
```

- If n is not a multiple of the number of threads per block TBP, a few threads will do no-ops

Review

- We write a kernel that looks like it runs on one thread
- We can launch that kernel on any number of threads
  - Use `kernel<<<(N+TPB-1)/TPB, TPB>>>()`
- Each thread knows its index in the block and grid
  - use `blockIdx.x` to get the block index
  - use `blockDim.x` to get the block size
  - use `threadIdx.x` to get the thread index

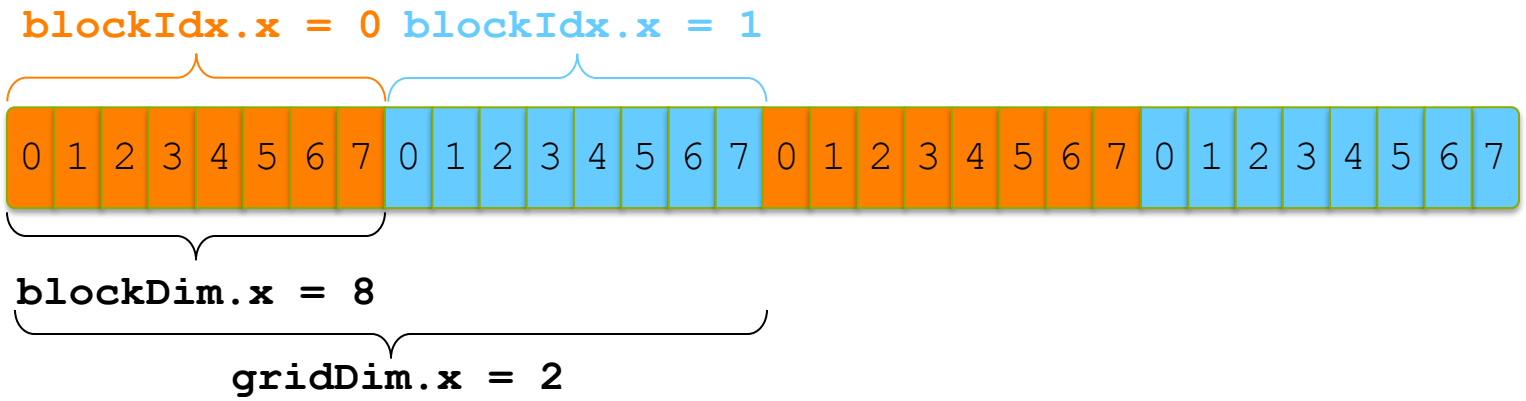
```
tid = threadIdx.x + blockIdx.x * blockDim.x
```

Handle arbitrary vector sizes (2)

- Maximum grid and block size is limited by hardware
- We thus need to
  - launch a fixed number of blocks and threads
  - rewrite our kernel for fixed grid and block size
- Built-in variable `gridDim.x` contains number of blocks in grid
- We can use this to compute strides
- For many kernels, performance will be optimal for a GPU-hardware dependent combination of grid / block size
  - Query hardware with CUDA calls to determine optimal kernel launch configuration at runtime

Handle arbitrary vector sizes (2)

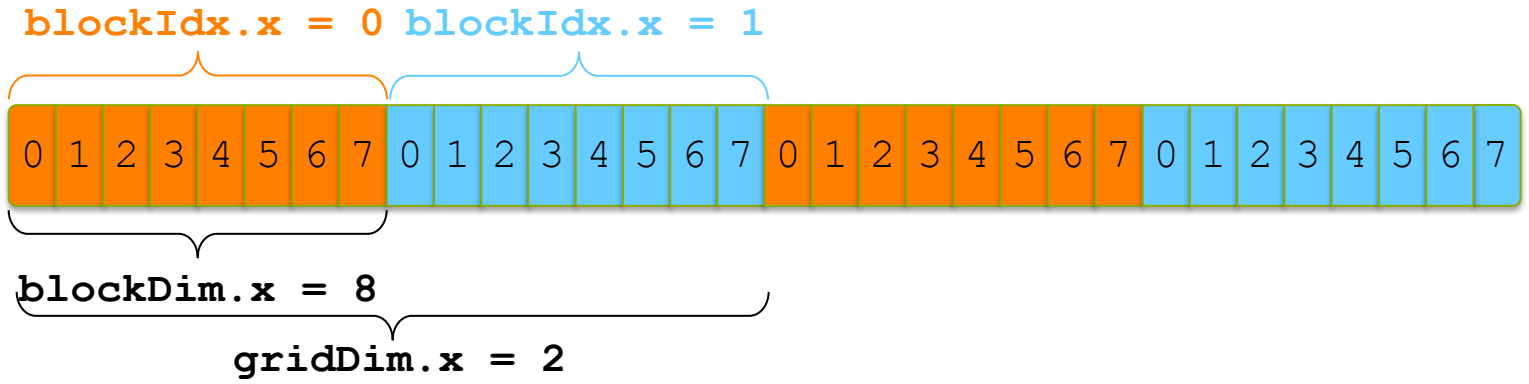
- Example: If we launch 2 blocks with 8 threads each, then kernels with
  - `blockIdx.x=0` need to work on blocks 0 and 2
  - `blockIdx.x=1` need to work on blocks 1 and 3



- Each kernel needs to know the stride required for accessing its data elements

```
int stride = blockDim.x * gridDim.x
```

Handle arbitrary vector sizes (2)



```
__global__ void add(int *a, int *b, int *c, int n){
        int tid = threadIdx.x + blockDim.x * blockIdx.x;
        int stride = blockDim.x * gridDim.x;
        while (tid < n) {
             c[tid] = a[tid] + b[tid];
                tid += stride
        }
}
```

- We can now launch a fixed number of kernels:

```
add<<<NBL,TPB>>>(d_a, d_b, d_c, N);
```

Multi-dimensional indexing

- CUDA supports
  - 3D grids of blocks and
  - 3D blocks of threads
- Convenient for mapping multi-dimensional problems (bitmaps, matrix operations etc)
- `grid3` data type, dimensions default to 1
- Example: launch grid of `(bx*by*bz)` blocks of `(tx*ty*tz)` threads with

```
kernel<<<dim3(bx,by,bz),dim3(tx,ty,tz)>>>();
```

Multi-dimensional indexing

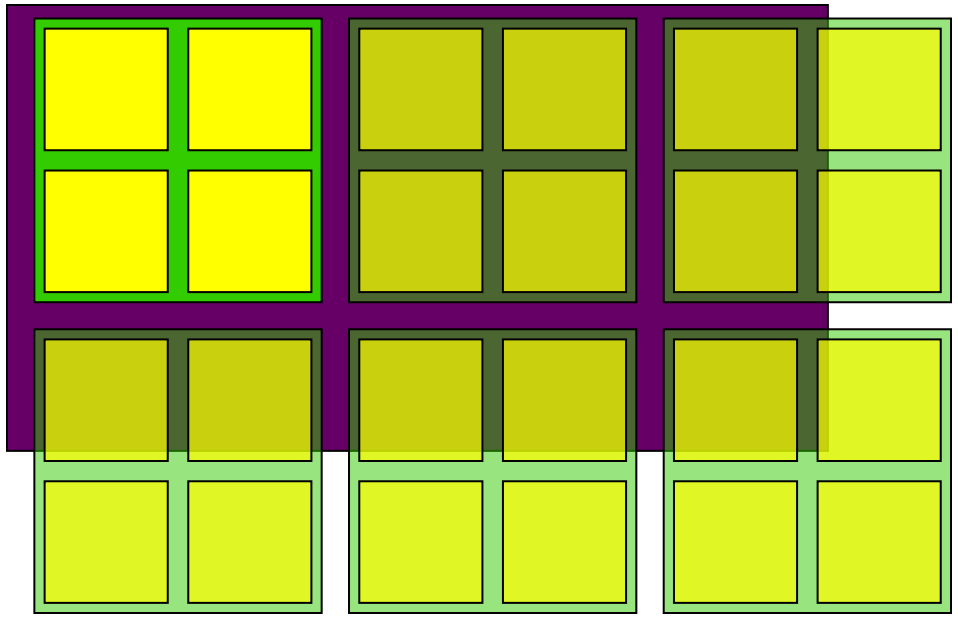
- Get grid dimension from
  `gridDim.x, gridDim.y, gridDim.z`
- Get block index in grid from
  `blockIdx.x, blockIdx.y, blockIdx.z`
- Get block dimension from
  `blockDim.x, blockDim.y, blockDim.z`
- Get thread index in block from
  `threadIdx.x, threadIdx.y, threadIdx.z`
- Use these to determine data access offsets and strides

Example: 2D array

Due to time consraints we will skip over
- **2D array example**
- **1D stencil example**
- **Histogram calculation**

I will leave these in the slides for you to look at / practice.

- Example: Kernel that squares a 2D array using a 2D grid of 2D blocks:



- Matrix (purple)
- 2D grid (green, 2x2)
- 2D blocks (yellow)
- (threads not shown)

Example: 2D array

Skipped

- Example: Kernel that squares a 2D array using a 2D grid of 2D blocks, assuming linear storage in memory:

```
__global__ void square(int *arr, int maxrow, int maxcol){
   // indices and strides
   int rowinit = threadIdx.x + blockDim.x * blockIdx.x;
   int colinit = threadIdx.y + blockDim.y * blockIdx.y;
   int rowstride = gridDim.x * blockDim.x;
   int colstride = gridDim.y * blockDim.y;

   // operate on all 2D "submatrices"
   for (int row = rowinit; row < maxrow; row += rowstride) {
      for (int col = colint; col < maxcol; col += colstride) {
         pos = row * maxcol + col
         arr[pos] *= arr[pos]
      }
   }
}
```

Example: 2D array

Skipped

- We can launch the kernel for example with a grid of (16*16) blocks of (16*16) threads, i.e. a total of 256*256 = 65,536 concurrent threads

```
#define NROW 2048
#define NCOL 512
int main(void){
    int h_a[NROW][NCOL];     // host copy
    int *d_a;                // device copy
    int size = NROW * NCOL * sizeof(int);

    // Allocate memory on device
    cudaMalloc((void **)&d_a, size);

    // Setup input values
    get_input_array(h_a);

    // Copy input data to device
    cudaMemcpy(d_a, h_a, size,
               cudaMemcpyHostToDevice);

    // Launch square() kernel
    dim3 gridSize(16,16);
    dim3 blockSize(16,16);
    square<<<gridSize,blockSize>>>(d_a, NROW, NCOL);

    // Copy results back to host
    cudaMemcpy(h_a, d_a, size,
               cudaMemcpyDeviceToHost);

    // Deallocate memory
    cudaFree(d_a);

    return 0;
}
```

Unified memory

Skipped

- Great to get started, simplifies programming

```
cudaMallocManaged(…);
```

- CUDA keeps track of memory location and migrates data from device to host and vice versa as required
- Developer needs to ensure that no race conditions are caused by simultaneous access to host/device memory
  - Pre-Pascal architecture will segfault; Pascal give wrong results
  - Therefore synchronize CPU/GPU (wait for kernel to finish):

```
cudaDeviceSynchronize();
```

Example: 2D array with unified memory

Skipped

```
#define NROW 2048
#define NCOL 512
int main(void){

    int size = NROW * NCOL * sizeof(int);
    int *array

    // Allocate managed memory, get data
    cudaMallocManaged(&array, size);
    get_input_array(array);

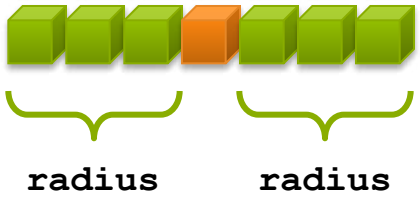
    // Launch square() kernel
    dim3 gridSize(16,16); dim3 blockSize(16,16);
    square<<<gridSize,blockSize>>>(array, NROW, NCOL);

    // Wait for kernel to finish before accessing data
    cudaDeviceSynchronize();
    print_results(array);
    cudaFree(array)
}
```

Communication among threads – shared memory Skipped

Example: 1D stencil

- 1D stencil for 1D array:
  - Each output element is the sum of input elements within a given radius
- If the radius is 3, then each output element is the sum of 7 input elements:

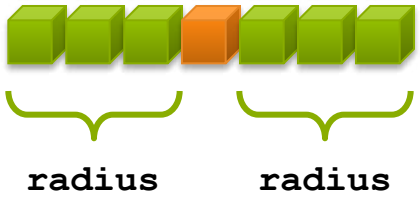


$$y'_i = y_i + \sum_{j=1}^{3} y_{i-j} + \sum_{j=1}^{3} y_{i+j}$$

Communication among threads – shared memory Skipped

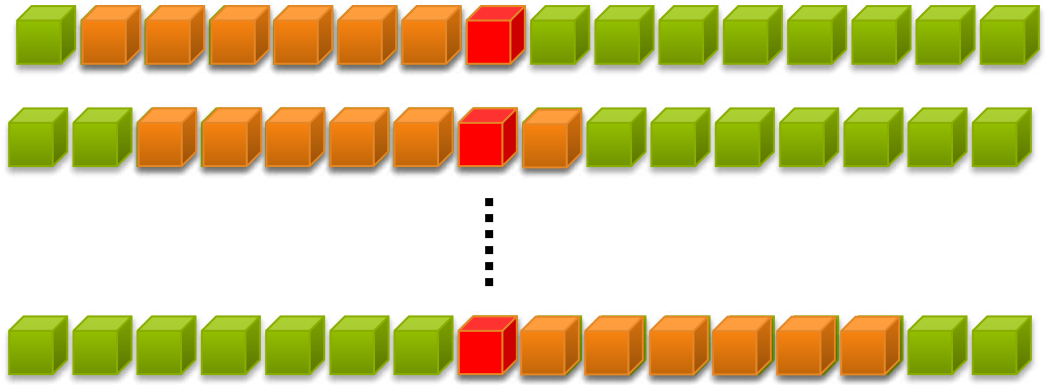
Example: 1D stencil

- 1D stencil for 1D array:
  - Each output element is the sum of input elements within a given radius
- If the radius is 3, then each output element is the sum of 7 input elements:



$$y'_i = y_i + \sum_{j=1}^{3} y_{i-j} + \sum_{j=1}^{3} y_{i+j}$$

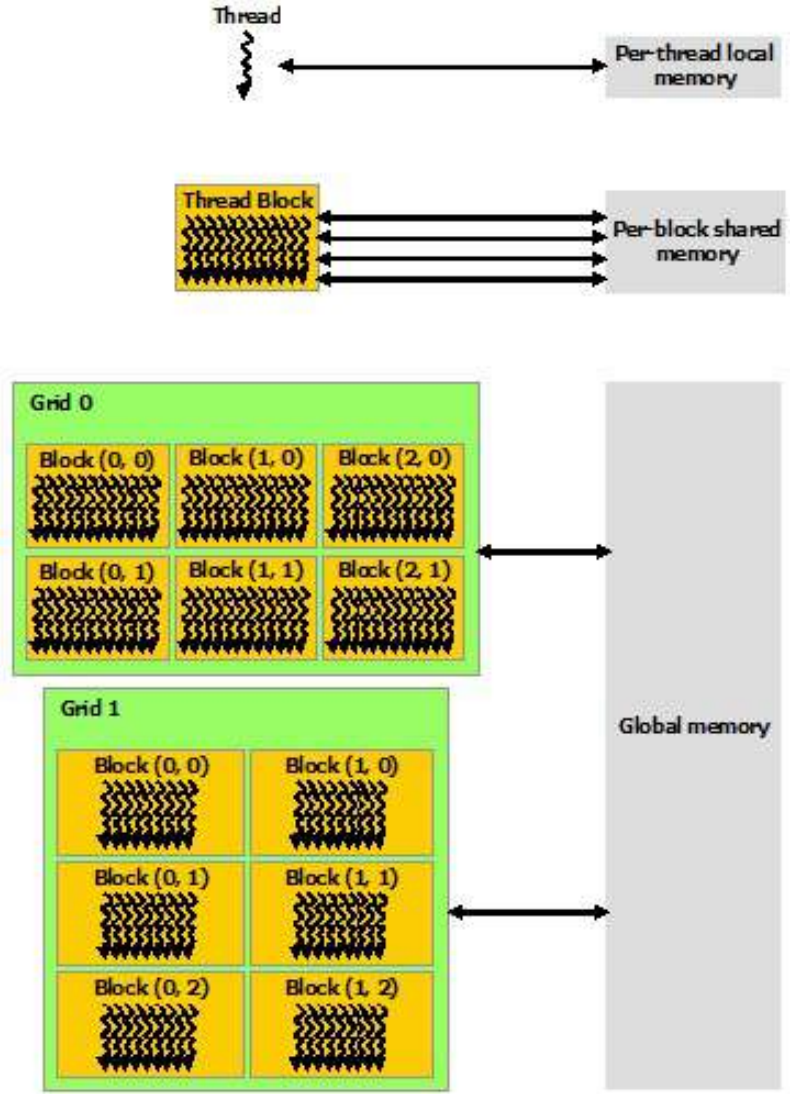
- Each thread processes one output element
  - `blockDim.x` elements are processed per block
- As a consequence, input elements have to be read several times from slow global memory
  - with radius 3, each input element is read 7 times!



Communication among threads – shared memory

Skipped

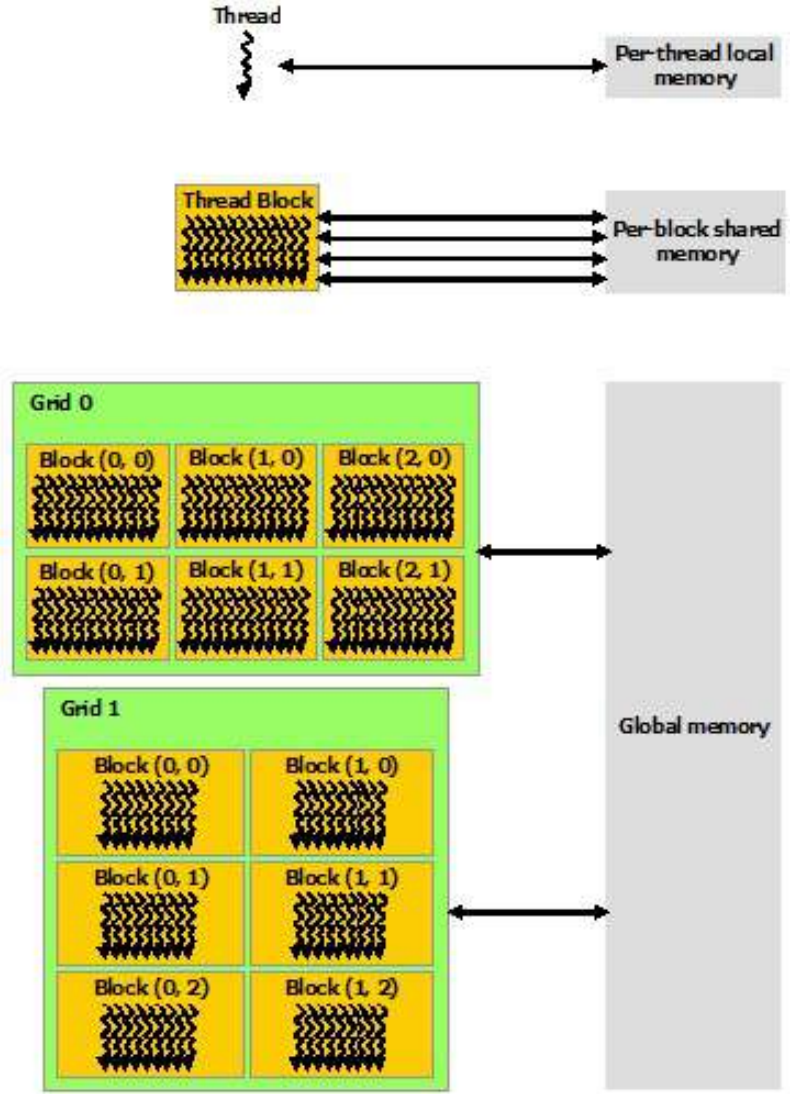
- Within a block, threads can share data via shared memory
- This is very fast on-chip memory
- Shared memory is user-managed
- Declare as `__shared__`, will be allocated per block
- Data in shared memory is not visible to other blocks



CUDA memory hierarchy

Skipped

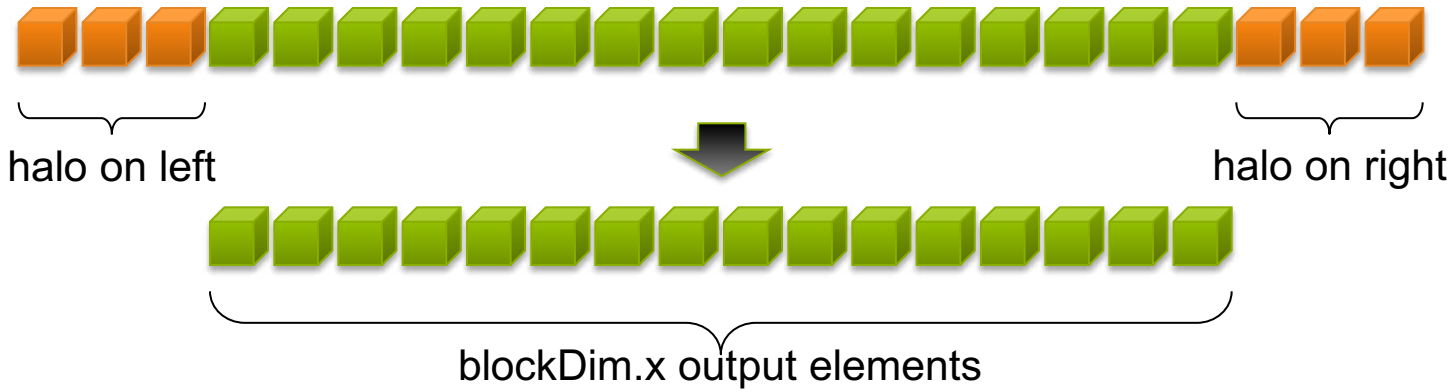
Memory	Latency (cycles)	Cached	Privacy
Global	100s	Yes	Application
Local	100s	Yes	Thread
Constant	1s-100s	Yes	Application
Texture	1s-100s	Yes	Application
Shared	1	–	Block
Register	1	–	Thread



1D stencil using shared memory

Skipped

- Cache data for use by different threads in shared memory
  - Read **`(blockDim.x + 2 * radius)`** input elements from global to shared memory
  - Compute **`blockDim.x`** output elements
  - Write **`blockDim.x`** output elements to global memory
  - Each block needs a "halo" of **`radius`** elements at each boundary



1D stencil using shared memory

Skipped

Data in shared memory

```
__global__ void stencil_1D(int *in, int *out){

    __shared__ int temp[BLOCK_SIZE + 2*RADIUS];

    int gindex = threadIdx.x + blockDim.x * blockIdx.x;
    int lindex = threadIdx.x + RADIUS
    int tid = threadIdx.x

}
```

1D stencil using shared memory

Skipped

```
__global__ void stencil_1D(int *in, int *out){

    __shared__ int temp[BLOCK_SIZE + 2*RADIUS];

    int gindex = threadIdx.x + blockDim.x * blockIdx.x;
    int lindex = threadIdx.x + RADIUS
    int tid = threadIdx.x

    // Read input elements into shared memory
    temp[lindex] = in[gindex];
    if (tid < RADIUS) {
        temp[lindex - RADIUS] = in[gindex - RADIUS];
        temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
    }

}
```

Data in shared memory

1D stencil using shared memory

Skipped

```
__global__ void stencil_1D(int *in, int *out){

    __shared__ int temp[BLOCK_SIZE + 2*RADIUS];

    int gindex = threadIdx.x + blockDim.x * blockIdx.x;
    int lindex = threadIdx.x + RADIUS
    int tid = threadIdx.x

    // Read input elements into shared memory
    temp[lindex] = in[gindex];
    if (tid < RADIUS) {
        temp[lindex - RADIUS] = in[gindex - RADIUS];
        temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
    }
    // Apply the stencil
    int result = 0;
    for (int offset = -RADIUS; offset <= RADIUS; offset++) {
        result += temp[lindex + offset];
    }
    // Store the result
    out[gindex] = result;
}
```

Data in shared memory

1D stencil using shared memory

Skipped

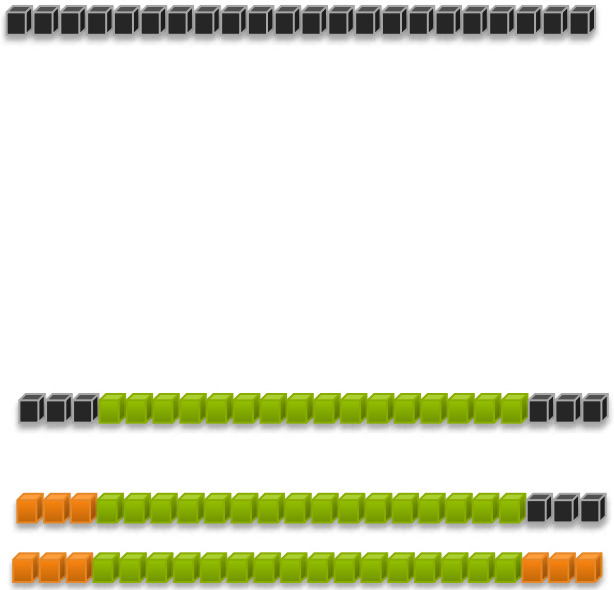
```
__global__ void stencil_1D(int *in, int *out){

    __shared__ int temp[BLOCK_SIZE + 2*RADIUS];

    int gindex = threadIdx.x + blockDim.x * blockIdx.x;
    int lindex = threadIdx.x + RADIUS
    int tid = threadIdx.x

    // Read input elements into shared memory
    temp[lindex] = in[gindex];
    if (tid < RADIUS) {
        temp[lindex – RADIUS] = in[gindex – RADIUS];
        temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
    }
    // Apply the stencil
    int result = 0;
    for (int offset = -RADIUS; offset <= RADIUS; offset++) {
        result += temp[lindex + offset];
    }
    // Store the result
    out[gindex] = result;
}
```

Data in shared memory



Unfortunately the code as it is will not work – Why ?

1D stencil using shared memory

Skipped

- We have a data race!
- Suppose thread 15 reads the halo before thread 0 has fetched it:

```
// Read input elements into shared memory
temp[lindex] = in[gindex]; // store at temp[18]
```

```
if (tid < RADIUS) {          // skipped by thread 15 (tid > RADIUS)
        temp[lindex - RADIUS] = in[gindex - RADIUS];
        temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
}

int result = 0;
result += temp[lindex+1];  // load from temp[19]
```

Thread synchronization in a block

Skipped

- To avoid race conditions we need to synchronize our threads in the block
  - used to prevent RAW / WAR / WAW hazards
- `void __syncthreads();`
- All threads in the block must reach the barrier
  - Similar to **`MPI_Barrier()`**
  - In conditional code, the condition must be uniform across the block to avoid deadlocks

1D stencil kernel using shared memory

Skipped

```
__global__ void stencil_1D(int *in, int *out){

    __shared__ int temp[BLOCK_SIZE + 2*RADIUS];

    int gindex = threadIdx.x + blockDim.x * blockIdx.x;
    int lindex = threadIdx.x + RADIUS
    int tid = threadIdx.x

    // Read input elements into shared memory
    temp[lindex] = in[gindex];
    if (tid < RADIUS) {
        temp[lindex - RADIUS] = in[gindex - RADIUS];
        temp[lindex + BLOCK_SIZE] = in[gindex + BLOCK_SIZE];
    }

    // Synchronize to ensure that all data is available
    __synthreads();
```

1D stencil kernel using shared memory

Skipped

```
    // Synchronize to ensure that all data is available
    __synthreads();

    // Apply the stencil
    int result = 0;
    for (int offset = -RADIUS; offset <= RADIUS; offset++) {
        result += temp[lindex + offset];
    }
    // Store the result
    out[gindex] = result;
}
```

This kernel

- improves performance by using shared memory
- avoids race conditions by synchronizing the threads within a block

1D stencil kernel using shared memory

Skipped

```
    // Synchronize to ensure that all data is available
    __synthreads();

    // Apply the stencil
    int result = 0;
    for (int offset = -RADIUS; offset <= RADIUS; offset++) {
        result += temp[lindex + offset];
    }
    // Store the result
    out[gindex] = result;
}
```

This kernel

- improves performance by using shared memory
- avoids race conditions by synchronizing the threads within a block

- Use **`__shared__`** to declare a variable / array in shared memory
  - Data is shared between threads in a block
  - Not visible to threads in other blocks
- Use **`__syncthreads()`** as a barrier
  - Required to prevent data hazards / race conditions

Constant memory

Skipped

In addition to shared memory, there is constant memory

- Read-only during kernel execution
- Located off-chip in global memory but accessed via dedicated hardware
  - broadcasts to all threads in a half-warp (16 threads), saving bandwidth
  - cached
- Define constant memory
  - `__constant__ int c_a[dimension];`
- Copy data into constant memory
  - `cudaMemcpyToSymbol(c_a, h_a, size);`

CUDA basics summary

Kernel

- In CUDA, a kernel is code (typically a function), that can be executed on the GPU.
- The kernel code operates in lock-step on the multiprocessors of the GPU.
  (In so-called warps, currently consisting of 32 threads)

Thread

- A thread is an execution of a kernel with a given index.
- Each thread uses its index to access a subset of data (e.g. array) to operate on.

Block

- Threads are grouped into blocks, which are guaranteed to execute on the same multiprocessor.
- Threads within a thread block can synchronize and share data

Grid

- Thread blocks are arranged into a grid of blocks.
- The number of threads per block times the number of blocks gives the total number of running threads.

CUDA basics summary

Threads, blocks, grids, warps

Grids

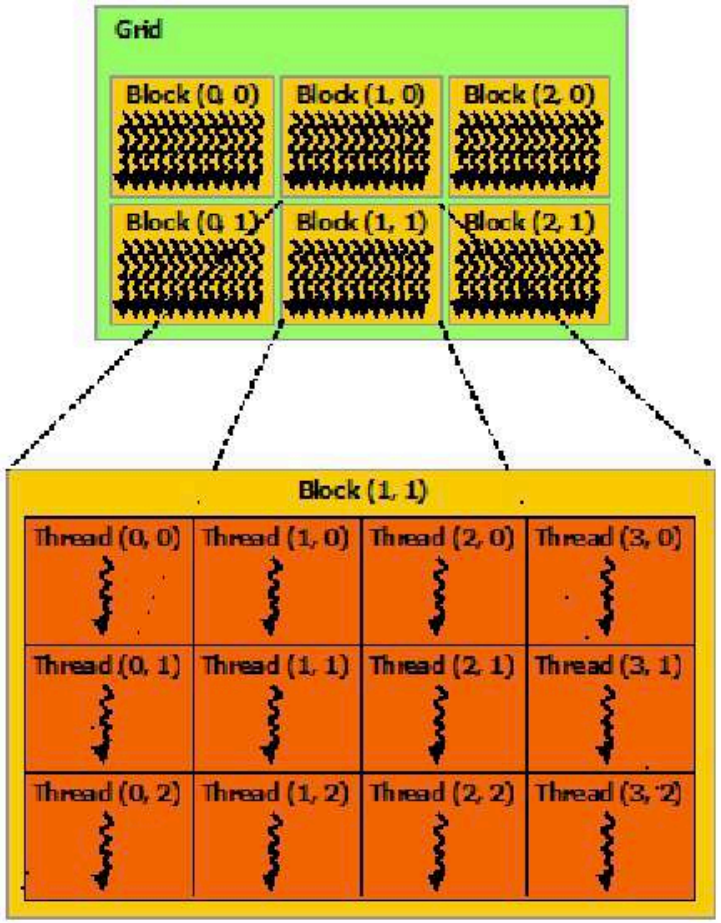
- Grids map to GPUs

Blocks

- Blocks map to the multiprocessors (MP)
- Blocks are never split across MPs
- Multiple blocks can execute simultaneously on an MP

Threads

- Threads are executed on stream processors (GPU cores)
- Warps are groups of threads that execute simultaneously, in lock-step (currently 32, not guaranteed to remain fixed).



CUDA basics summary

CUDA built-in variables

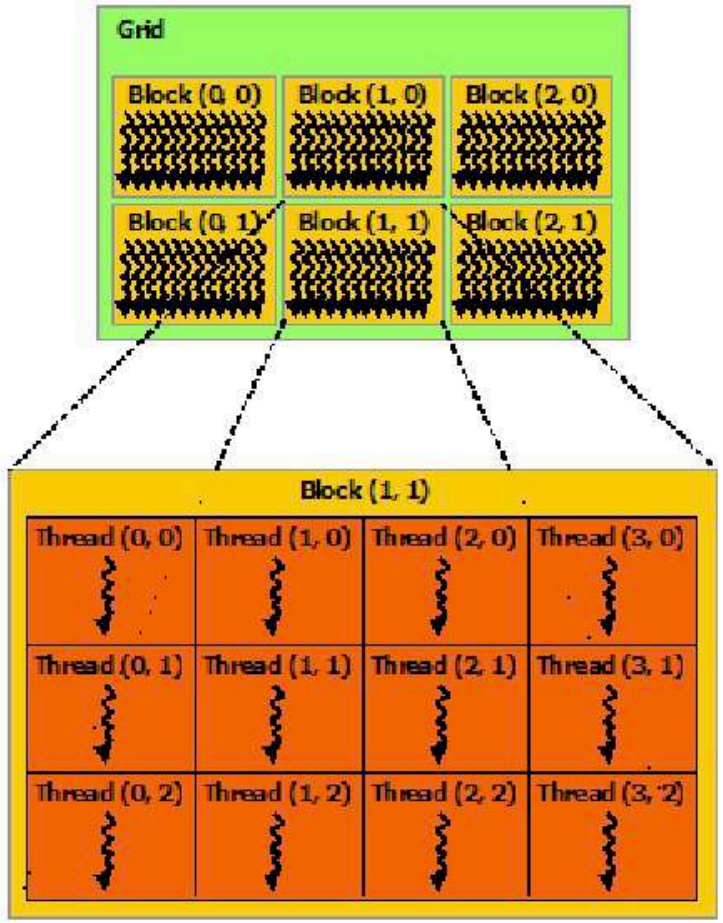
- Following variables allow to compute the ID of each individual thread that is executing in a grid block.

Block indexes

- `gridDim.x, gridDim.y, gridDim.z (unused)`
- `blockIdx.x, blockIdx.y, blockIdx.z`
- Variables that return the grid dimension (number of blocks) and block ID in the x-, y-, and z-axis.

Thread indexes

- `blockDim.x, blockDim.y, blockDim.z`
- `threadIdx.x, threadIdx,y, threadIdx.z`
- Variables that return the block dimension (number of threads per block) and thread ID in the x-, y-, and z-axis.



Example in the figure is executing 72 threads

- (3 x 2) blocks = 6 blocks
- (4 x 3) threads per block = 12 threads per block

CUDA basics summary

__global__ keyword

- Function that executes on the device (GPU), must return `void`, and is called from host code.

```
__global__ vector_add_kernel(int *a, int *b, int *c, int n){
     int tid = threadIdx.x + blockDim.x * blockIdx.x;
     int stride = blockDim.x * gridDim.x;
     while (tid < n) {
            c[tid] = a[tid] + b[tid];
            tid += stride;
     }
 }
```

CUDA API handles device memory

- `cudaMalloc()`, `cudaFree()`, `cudaMemcpy()`
- Equivalent to C `malloc()`, `free()`, `memcpy()`
- `cudaMemcpy()` is used to transfer data between CPU and GPU memory.

CUDA kernel launch specification

- Triple angle bracket determines grid and block size (i.e. total number of threads) for kernel launch:

```
vector_add_kernel<<<dim3(bx,by,bz), dim3(tx,ty,tz)>>>(d_a, d_b, d_c, N);
```

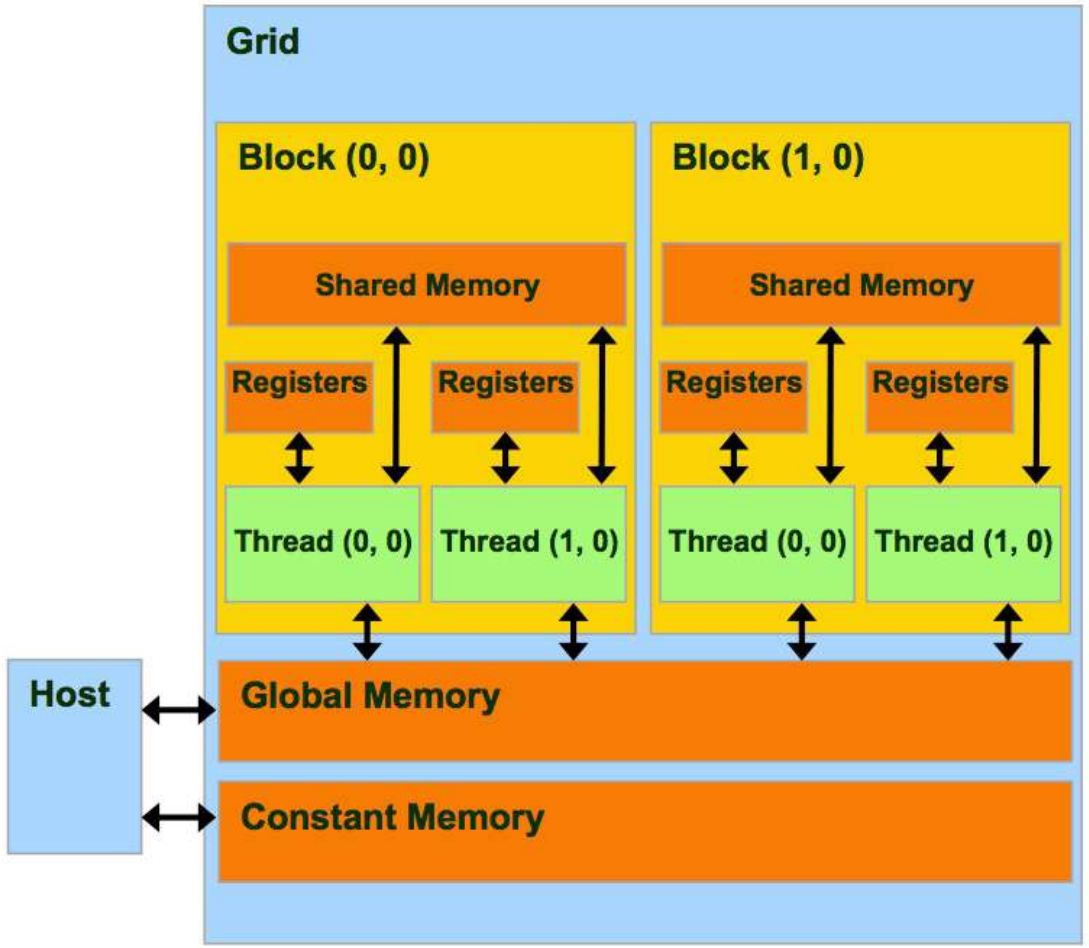
CUDA basics: Memory overview

CUDA memory hierarchy

- Host memory (x86 server)
- Device memory (GPU)

Device memory

- Global memory
  visible to all threads, slow
- Shared memory
  visible to all threads in a block, fast on-chip
- Registers
  per-thread memory, fast on-chip
- Local memory
  per-thread, slow, stored in Global Memory space
- Constant memory
  visible to all threads, read only, off-chip, cached
  broadcast to all threads in a half-warp (16 threads)



General CUDA programming strategy

Avoid data transfers between CPU and GPU

- These are slow due to low PCI express bus bandwidth

Minimize access to global memory

- Hide memory access latency by launching many threads

Take advantage of fast shared memory by tiling data

- Partition data into subsets that fit into shared memory
- Handle each data subset with one thread block
- Load the subset from global to shared memory using multiple threads to exploit parallelism in memory access
- Perform computation on data subset in shared memory (each thread in thread block can access data multiple times)
- Copy results from shared memory to global memory

General CUDA programming strategy

Use of constant memory for data that is constant during run time

- Data that is accessed by all threads within a block (half-warp, actually) at the same time
  - this reduces memory bandwidth requirements
- Do not use constant memory if threads access different elements of the data
  - half-warps can place only a single read-request at a time
  - if threads need different data from constant memory, these reads get serialized

CUDA Example: Matrix-matrix multiply

```
float* host_A, host_B, host_C;
float* device_A, device_B, device_C;

// Allocate host memory
host_A = (float*) malloc(mem_size_A);
host_B = (float*) malloc(mem_size_B);
host_C = (float*) malloc(mem_size_C);

// Allocate device memory
cudaMalloc((void**) &device_A, mem_size_A);
cudaMalloc((void**) &device_B, mem_size_B);
cudamalloc((void**) &device_C, mem_size_C);

// Set up the initial values of A and B here.
...
```

Explain only concepts without following details

Skip if there is not sufficient time

CUDA Example: Matrix-matrix multiply - 2

```
// copy host memory to device
cudaMemcpy(device_A, host_A, mem_size_A, cudaMemcpyHostToDevice);
cudaMemcpy(device_B, host_B, mem_size_B, cudaMemcpyHostToDevice);

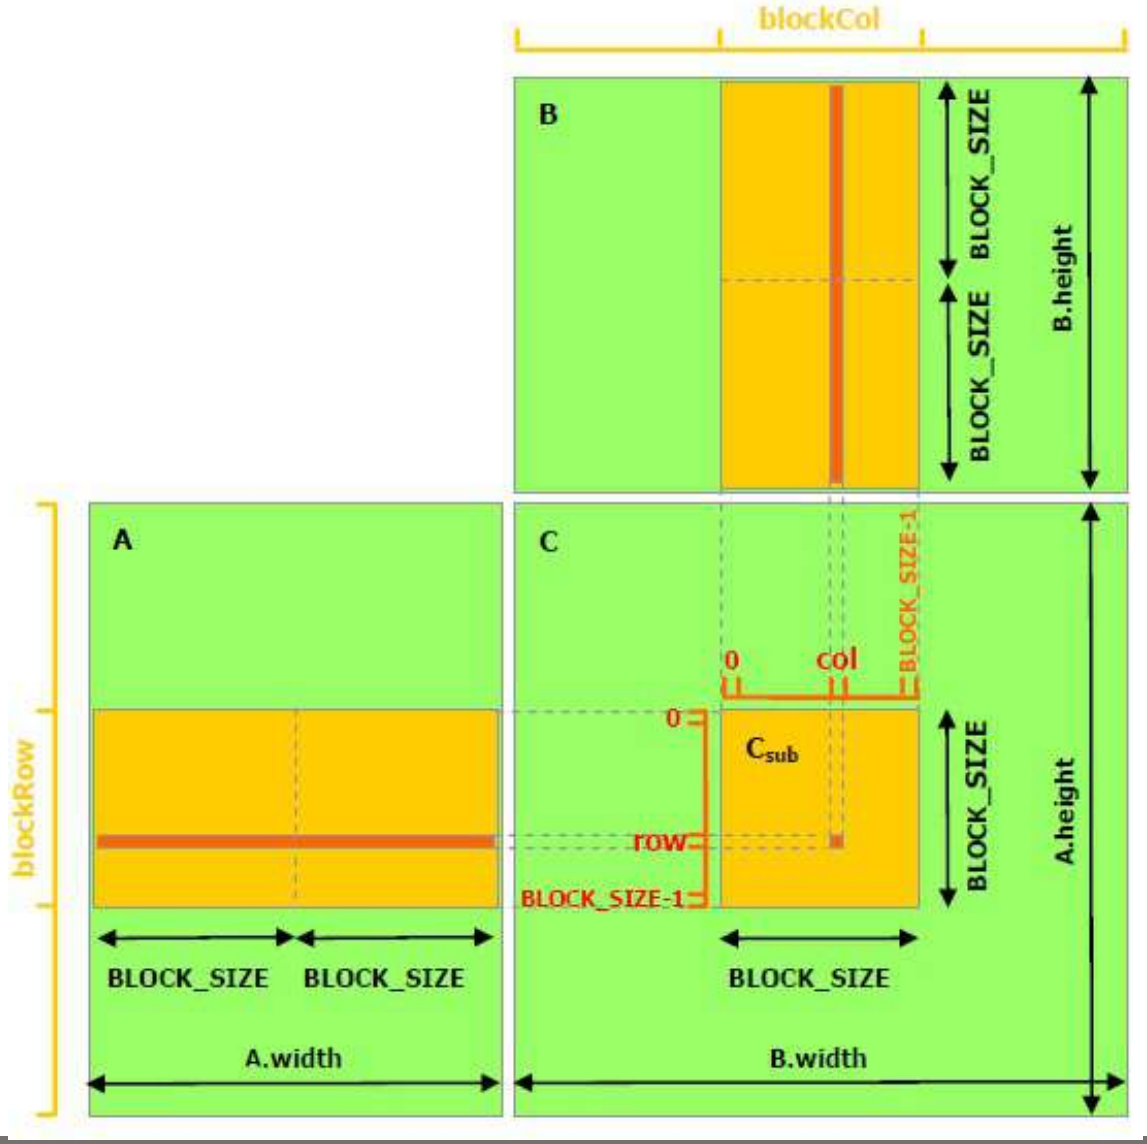
// setup execution parameters
dim3 threads(BLOCK_SIZE, BLOCK_SIZE);
dim3 grid(WC / threads.x, HC / threads.y);

// execute the kernel
matrixMul<<< grid, threads >>>(device_C, device_A, device_B, WA, WB);

// copy result from device to host
cudaMemcpy(host_C, device_C, mem_size_C, cudaMemcpyDeviceToHost);

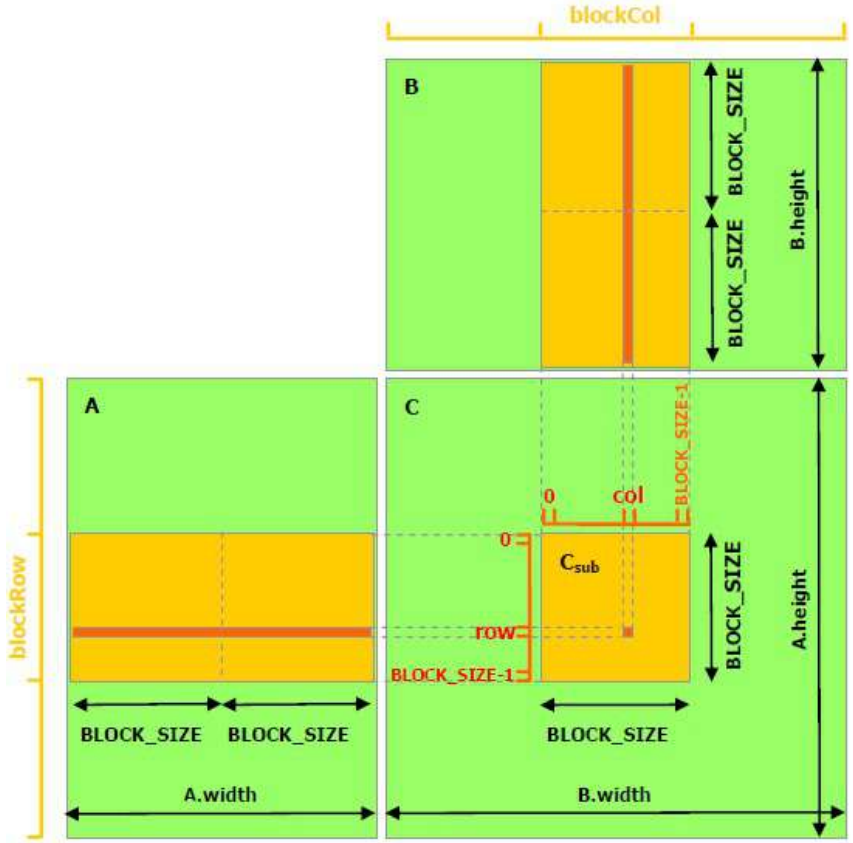
// Free host and device memory
...
```

CUDA Example: Matrix-matrix multiply kernel



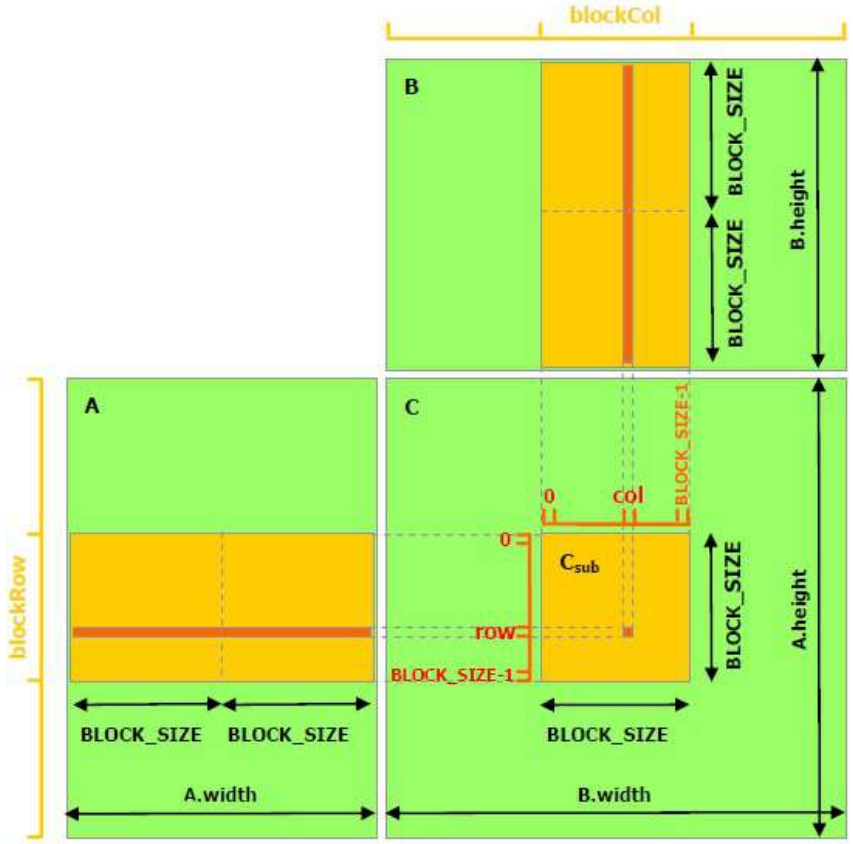
CUDA Example: Matrix-matrix multiply kernel

```
__global__ void matrixMul( float* C, float* A, float* B, int wA, int wB)
{
  // Block index
  int bx = blockIdx.x;
  int by = blockIdx.y;
  // Thread index
  int tx = threadIdx.x;
  int ty = threadIdx.y;
  // Index of the first sub-matrix of A processed by the block
  int aBegin = wA * BLOCK_SIZE * by;
  // Index of the last sub-matrix of A processed by the block
  int aEnd = aBegin + wA - 1;
  // Step size used to iterate through the sub-matrices of A
  int aStep = BLOCK_SIZE;
  // Index of the first sub-matrix of B processed by the block
  int bBegin = BLOCK_SIZE * bx;
  // Step size used to iterate through the sub-matrices of B
  int bStep = BLOCK_SIZE * wB;
  // Csub is used to store the element of the block sub-matrix
  // that is computed by the thread
  float Csub = 0;
```



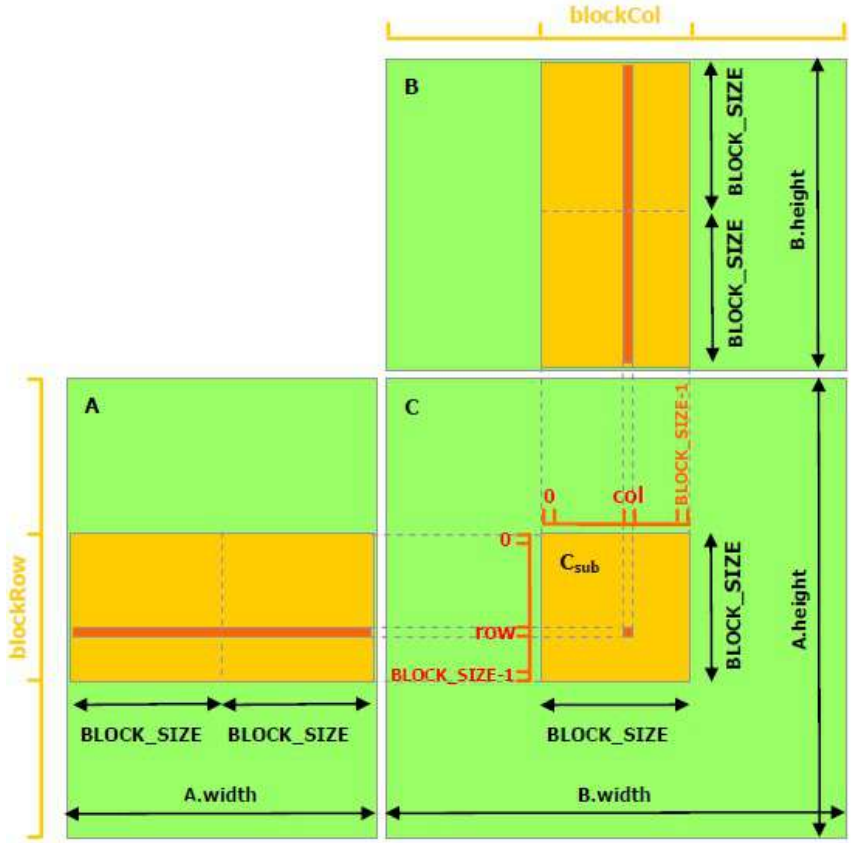
CUDA Example: Matrix-matrix multiply kernel – 2

```
// Loop over all the sub-matrices of A and B
// required to compute the block sub-matrix
for (int a = aBegin, b = bBegin;
     a <= aEnd;
     a += aStep, b += bStep) {
  // Declaration of the shared memory array As
  // store the sub-matrix of A
  __shared__ float As[BLOCK_SIZE][BLOCK_SIZE];
  // Declaration of the shared memory array Bs
  // store the sub-matrix of B
  __shared__ float Bs[BLOCK_SIZE][BLOCK_SIZE];
  // Load the matrices from device memory
  // to shared memory; each thread loads
  // one element of each matrix
  AS(ty, tx) = A[a + wA * ty + tx];
  BS(ty, tx) = B[b + wB * ty + tx];
  // Synchronize to make sure the matrices are loaded
  __syncthreads();
```



CUDA Example: Matrix-matrix multiply kernel – 3

```
    // Multiply the two matrices together;
    // each thread computes one element of the block sub-matrix
    for (int k = 0; k < BLOCK_SIZE; ++k)
      Csub += AS(ty, k) * BS(k, tx);
    // Synchronize to make sure that the preceding
    // computation is done before loading two new
    // sub-matrices of A and B in the next iteration
    __syncthreads();
  }
  // Write the block sub-matrix to device memory;
  // each thread writes one element
  int c = wB * BLOCK_SIZE * by + BLOCK_SIZE * bx;
  C[c + wB * ty + tx] = Csub;
}
```



CUDA Example: Matrix-matrix multiply summary

Summary

- We made use of a variety of CUDA features including
- 2D grids and blocks
- Shared memory
- Thread synchronization

Note

- In reality we would not write a matrix-matrix multiplication function
- The CUDA implementation of BLAS is highly optimized for GPUs

Avoiding race conditions with atomic operations

Atomic operations

- An atomic operation cannot be divided into several operations
- What happens when we increment a counter?

```
i++;
```

- This consists of three steps
  - 1) Read the value stored at the address of `i`
  - 2) Add 1 to the value read in step 1)
  - 3) Write the result back to the address of `i`
- What happens if multiple threads increment the counter?

Avoiding race conditions with atomic operations

Atomic operations

- An atomic operation cannot be divided into several operations
- What happens when we increment a counter?

```
i++;
```

- This consists of three steps
  - 1) Read the value stored at the address of `i`
  - 2) Add 1 to the value read in step 1)
  - 3) Write the result back to the address of `i`
- What happens if multiple threads increment the counter?
- If multiple threads modify an address, the result is unpredictable
- Atomic operations are performed without interference from other threads
- Atomic operations are available on newer GPUs (efficient since Kepler chips) and can operate on global or shared memory
  - **`atomicAdd()`, `atomicSub()`, `atomicMin()`,** …
  - etc. see programming guide for full list
- Use wisely – code execution will be serialized

Example: Histogram

Skipped

- Assume data set of 8-bit (1 byte) values
- Compute occurrence of each of the 256 possible values
- Serial CPU code:

```
#define SIZE (100*1024*1024)
int main(void){
    unsigned char buffer[SIZE];
    unsigned int histo[256];

    get_data(buffer,SIZE);          //read data

    for (int i=0; i<256; i++)       //initialize to zero
        histo[i] = 0;

    for (int i=0; i<SIZE; i++)      //compute histogram
        histo[buffer[i]]++;

    return 0;
}
```

Histogram CUDA code

Skipped

- Using atomic add operation to avoid data races

```
#define SIZE (100*1024*1024)

// histogram kernel
__global__ histo_kernel(unsigned char *buffer,
                        int size, unsigned int *histo){

    int tid = threadIdx.x + blockIdx.x * blockDim.x;
    int stride = blockDim.x *gridDim.x;

    while (tid < size) {
        atomicAdd( &(histo[buffer[tid]]), 1 );
        tid += stride;
    }
}
```

- This will work – but with terrible performance – why?

Histogram CUDA code

Skipped

- Using atomic add operation to avoid data races

```
#define SIZE (100*1024*1024)

// histogram kernel
__global__ histo_kernel(unsigned char *buffer,
                        int size, unsigned int *histo){

    int tid = threadIdx.x + blockIdx.x * blockDim.x;
    int stride = blockDim.x *gridDim.x;

    while (tid < size) {
        atomicAdd( &(histo[buffer[tid]]), 1 );
        tid += stride;
    }
}
```

- This will work – but with terrible performance – why?

Bad performance because

- the kernel does very little work
- thousands of threads access few (256) memory locations with atomic add operations

Improve performance by using shared memory

- write operations to shared memory are fast
- fewer threads will try to access the same memory locations with the atomic add operation

Histogram CUDA code

Skipped

Histogram kernel with shared memory

```
#define SIZE (100*1024*1024)

// histogram kernel
__global__ histo_kernel(unsigned char *buffer,
                  int size, unsigned int *histo){

    // shared memory,
    // assume 256 threads per block
    __shared__ unsigned int temp[256];
    temp[threadIdx.x] = 0;
    __syncthreads();

    int tid = threadIdx.x + blockIdx.x * blockDim.x;
    int stride = blockDim.x *gridDim.x;
```

```
    // compute histogram in shared memory
    // for this block
    while (tid < size) {
        atomicAdd( &(temp[buffer[tid]]), 1 );
        tid += stride;
    }
    __syncthreads();

    // now merge each block's histogram
    // into global memory
    // again assuming 256 threads per block
    atomicAdd( &(histo[threadIdx.x]),
                              temp[threadIdx.x] );
}
```

Histogram CUDA code

Skipped

Histogram host code

```
int main(void) {

    // host and device memory / pointers
    unsigned char h_buffer[SIZE], *d_buffer;
    unsigned int h_histo[256], *d_histo;

    // get our input data
    get_data(buffer, SIZE);

    // allocate device memory
    cudaMalloc( (void**)&d_buffer, SIZE);
    cudaMalloc( (void**)&d_histo,
                    256 * sizeof(int) );

    // copy data to device
    cudaMemcpy( d_buffer, h_buffer, SIZE,
                    cudaMemcpyHostToDevice);
```

```
    // initialize histogram to zero
    cudaMemset(d_histo, 0, 256);

    // launch kernel
    histo_kernel<<<32,256>>>(d_buffer,
                                SIZE, d_histo);

    // copy results back
    cudaMemcpy( h_histo, d_histo,
      256*sizeof(int), cudaMemcpyDeviceToHost);

    // free memory
    cudaFree(d_buffer); cudaFree(d_histo);

    // print our histogram
    print_histogram(h_histo);

    return 0;
}
```

CUDA Toolkit Samples

CUDA Toolkit Samples

- CUDA Toolkit code samples are available for CUDA 10.2. Copy into your home directory:

```
[agoetz@exp-8-59 ~]$ cp -r /cm/shared/apps/cuda10.2/sdk/10.2.89 ./CUDA_samples
```

- Explore CUDA Toolkit samples – great resource!

```
[agoetz@exp-8-59 ~]$ cd CUDA_samples/
[agoetz@exp-8-59 CUDA_samples]$ ls
0_Simple      3_Imaging       6_Advanced        common    opencl
1_Utilities   4_Finance       7_CUDALibraries   EULA.txt  verify_cuda10.2.sh
2_Graphics    5_Simulations   bin               Makefile  verify_opencl.sh
```

- Compile CUDA Toolkit samples

```
[agoetz@exp-8-59 CUDA_samples]$ make -k -j 10
make[1]: Entering directory `/home/agoetz/CUDA_samples/0_Simple/simpleMultiCopy'
/usr/local/cuda-10.2/bin/nvcc -ccbin g++ -I../../common/inc  -m64    -gencode
arch=compute_30,code=sm_30 -gencode arch=compute_35,code=sm_35 -gencode
...
arch=compute_75,code=sm_75 -gencode arch=compute_75,code=compute_75 -o simpleMultiCopy.o -c
simpleMultiCopy.cu
```

CUDA Toolkit Samples

CUDA Toolkit Samples

- Compilation takes a while, executables will reside in sub directory `bin/x86_64/linux/release/`
- Can compile individual examples, e.g. `deviceQuery`, which prints information on available GPUs

```
[agoetz@exp-1-57 CUDA_examples]$ cd 1_Utilities/deviceQuery
[agoetz@exp-1-57 CUDA_examples]$ make
/usr/local/cuda-10.2/bin/nvcc -ccbin g++ -I../../common/inc  -m64    -gencode arch=com
...
[agoetz@exp-1-57 deviceQuery]$ ./deviceQuery
./deviceQuery Starting...

 CUDA Device Query (Runtime API) version (CUDART static linking)

Detected 1 CUDA Capable device(s)

Code samples from this course

- In SI 2020 Github repository
  https://github.com/sdsc/sdsc-summer-institute-2021
  directory **`4.1a_GPU_Computing_and_Programming`**

- Directory **`4.1a_GPU_Computing_and_Programming/cuda-samples`**
  - "Hello world"
  - Addition, vector addition
  - Squaring matrix elements (not discussed)
  - 1D stencil (not discussed)

If you have not done so, please clone the repository now

- Check the README files
- Compile and run CUDA examples
- Try the exercises (look for **FIXME** comments and try to replace with correct code)

Directive based GPU programming with OpenACC

Partially based on material by
Mark Harris (Nvidia)

Directive based programming

OpenACC

- See https://www.openacc.org
- Open standard for expressing accelerator parallelism
- Designed to make porting to GPUs easy, quick, and portable
- OpenMP-like compiler directives language
  - If the compiler does not understand the directives, it will ignore them.
  - Same code can work with or without accelerators.
- Fortran and C
- Full support by PGI compilers and Cray compilers on Crays
- Partial support by GNU compilers (experimental since version 5.1)
- Also some less commonly used and experimental compilers

OpenMP

- See https://www.openmp.org
- Not mature for GPUs, will not discuss here

Directive based programming

PGI Community Edition

- See https://developer.nvidia.com/openacc-toolkit
- Community Edition is free
- PGI Accelerator Fortran / C / C++ compilers
- Support for OpenMP and OpenACC
- pgprof performance profiler
- GPU-enabled libraries
- OpenACC code samples

Note: Can also use Nvidia HPC SDK

Activate on Expanse GPU nodes

```
$> module purge
$> module reset
$> module load pgi
```

- Currently loads version 20.4 by default
- Versions 19.7 and 18.10 also available

A simple OpenACC exercise: SAXPY

SAXPY in C

```
void saxpy(int n,
           float a,
           float *x,
           float *restrict y)
{
#pragma acc kernels
  for (int i = 0; i < n; ++i)
    y[i] = a*x[i] + y[i];
}

...
// Perform SAXPY on 1M elements
saxpy(1<<20, 2.0, x, y);
...
```

SAXPY in Fortran

```
subroutine saxpy(n, a, x, y)
  real :: x(:), y(:), a
  integer :: n, i
!$acc kernels
  do i=1,n
    y(i) = a*x(i)+y(i)
  enddo
!$acc end kernels
end subroutine saxpy

...
! Perform SAXPY on 1M elements
call saxpy(2**20, 2.0, x_d, y_d)
...
```

OpenACC directives syntax

Fortran

```
!$acc directive [clause [,] clause] …]
```

Often paired with a matching end directive surrounding a structured code block

```
!$acc end directive
```

C

```
#pragma acc directive [clause [,] clause] …]
```

Often followed by a structured code block

`kernels` construct

```
!$acc kernels [clause ...]
  structured code block
!$acc end kernels
```

`kernels` construct

```
#pragma acc kernels [clause …]
{ structured code block }
```

Clauses

```
if( condition )
async( expression )
```

or data clauses

OpenACC directives syntax

Data clauses

`copy ( list )`	Allocates memory on GPU and copies data from host to GPU when entering region and copies data to the host when exiting region.
`copyin ( list )`	Allocates memory on GPU and copies data from host to GPU when entering region.
`copyout ( list )`	Allocates memory on GPU and copies data to the host when exiting region.
`create ( list )`	Allocates memory on GPU but does not copy.
`present ( list )`	Data is already present on GPU from another containing data region.

and `present_or_copy[in|out], present_or_create, deviceptr`.

Complete SAXPY code

Trivial first example

- Apply a loop directive
- Learn compiler commands

```
#include <stdlib.h>

void saxpy(int n,
           float a,
           float *x,
           float * restrict y)
{
#pragma acc kernels
  for (int i = 0; i < n; ++i)
    y[i] = a * x[i] + y[i];
}
```

```
int main(int argc, char **argv)
{
  int N = 1<<20; // 1 million floats

  float *x = (float*)malloc(N *
sizeof(float));
  float *y = (float*)malloc(N *
sizeof(float));

  for (int i = 0; i < N; ++i)
  {
    x[i] = 2.0f;
    y[i] = 1.0f;
  }

  saxpy(N, 3.0f, x, y);

  return 0;
}
```

Compile and run SAXPY OpenACC code

- C:

```
pgcc -acc -ta=tesla -Minfo=accel -o saxpy_acc saxpy.c
```

- Fortran:

```
pgf90 -acc -ta=tesla -Minfo=accel -o saxpy_acc saxpy.f90
```

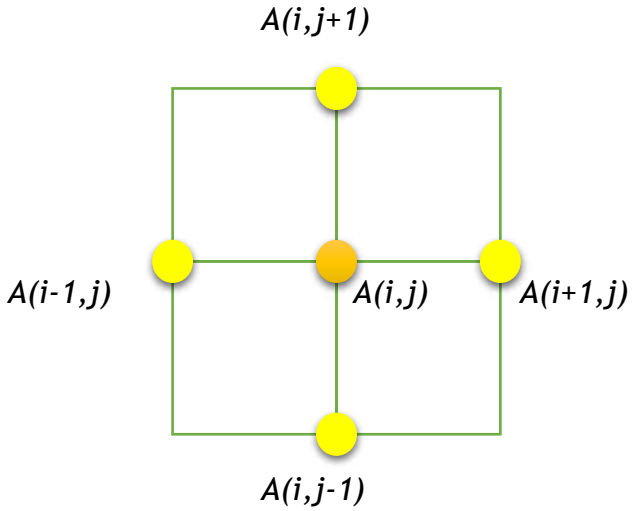
- Compiler output:

```
pgcc saxpy.c -acc -ta=tesla -Minfo=accel -o saxpy-gpu.x
saxpy:
      8, Generating copyin(x[:n])
         Generating copy(y[:n])
      9, Loop is parallelizable
         Accelerator kernel generated
         Generating Tesla code
          9, #pragma acc loop gang, vector(128) /* blockIdx.x
threadIdx.x */
```

OpenACC example: Jacobi iteration

Iteratively converges to correct value (e.g. Temperature),
by computing new values at each point from the average of neighboring points.

- Common, useful algorithm
- Example: Solve Laplace equation in 2D: $\Delta\varphi(x,y) = 0$



$$A_{k+1}(i,j) = \frac{A_k(i-1,j) + A_k(i+1,j) + A_k(i,j-1) + A_k(i,j+1)}{4}$$

OpenACC example: Jacobi iteration

```
while ( error > tol && iter < iter_max )
{
  error=0.0;

  for( int j = 1; j < n-1; j++) {
    for(int i = 1; i < m-1; i++) {

      Anew[j][i] = 0.25 * (A[j][i+1] + A[j][i-1] +
                           A[j-1][i] + A[j+1][i]);

      error = max(error, abs(Anew[j][i] - A[j][i]);
    }
  }

  for( int j = 1; j < n-1; j++) {
    for( int i = 1; i < m-1; i++ ) {
      A[j][i] = Anew[j][i];
    }
  }

  iter++;
}
```

Iterate until converged

Iterate across matrix elements

Calculate new value from neighbors

Compute max error for convergence

Swap input/output arrays

OpenACC example: Jacobi iteration – first attempt

```
while ( error > tol && iter < iter_max )
{
  error=0.0;

  #pragma acc kernels
  for( int j = 1; j < n-1; j++) {
    for(int i = 1; i < m-1; i++) {

      Anew[j][i] = 0.25 * (A[j][i+1] + A[j][i-1] +
                           A[j-1][i] + A[j+1][i]);

      error = max(error, abs(Anew[j][i] - A[j][i]);
    }
  }

  #pragma acc kernels
  for( int j = 1; j < n-1; j++) {
    for( int i = 1; i < m-1; i++ ) {
      A[j][i] = Anew[j][i];
    }
  }

  iter++;
}
```

Execute GPU kernel for loop nest

Execute GPU kernel for loop nest

OpenACC example: Jacobi iteration – first attempt

Compiler output

```
pgf90 -acc -ta=tesla -Minfo=accel -o jacobi-pgf90-acc-v1.x jacobi-acc-v1.f90
laplace:

         59, !$acc loop gang, vector(128) ! blockidx%x threadidx%x
```

OpenACC example: Jacobi iteration – first attempt

SDSC Comet CPU: Intel Xeon E5-2680 v3 GPU: NVIDIA Tesla K80 (using single GPU)

Execution	Time (s)	Speedup
CPU 1 OpenMP thread	69	--
CPU 2 OpenMP threads	36	1.92x
CPU 4 OpenMP threads	22	3.14x
CPU 6 OpenMP threads	17	4.06x
OpenACC GPU	501	0.03x FAIL

Compiler:
pgcc 17.5-0

CPU flags:
-fastsse -O3 -mp [-Minfo=mp]

GPU flags:
-acc [-Minfo=accel]

Speedup vs. 1 CPU core

Speedup vs. 6 CPU cores

OpenACC example: Jacobi iteration – first attempt

```
export PGI_ACC_TIME=1    ! Activate profiling, then run again
```

```
Accelerator Kernel Timing data
/server-home1/agoetz/UCSD_Phys244/2017/openacc-samples/laplace-2d/jacobi-acc-v1.f90
  laplace  NVIDIA  devicenum=0
    time(us): 89,612,134
 ..... <snip – some lines cut>

        63: data copyout transfers: 8000
            device time(us): total=20,278,000 max=2,618 min=2,498 avg=2,534
```

22.5 seconds

1.5 seconds

What went wrong?

- We spent all the time with data transfers between host and device

OpenACC example: Jacobi iteration – first attempt

Excessive data transfers

```
while ( error > tol && iter < iter_max )
{
  error=0.0;
```

A, Anew resident on host

Copy

A, Anew resident on accelerator

```
#pragma acc kernels
for( int j = 1; j < n-1; j++) {
  for( int i = 1; i < m-1; i++) {
    Anew[j][i] = 0.25 * (A[j][i+1] + A[j][i-1] +
                         A[j-1][i] + A[j+1][i]);
    error = max(error, abs(Anew[j][i] - A[j][i]);
  }
}
```

These copies happen every iteration of the outer while loop!

A, Anew resident on accelerator

Copy

A, Anew resident on host

```
  ...
}
```

OpenACC example: Jacobi iteration – second attempt

```
#pragma acc data copy(A), create(Anew)
while ( error > tol && iter < iter_max ) {
  error=0.0;

#pragma acc kernels
  for( int j = 1; j < n-1; j++) {
    for(int i = 1; i < m-1; i++) {

      Anew[j][i] = 0.25 * (A[j][i+1] + A[j][i-1] +
                           A[j-1][i] + A[j+1][i]);

      error = max(error, abs(Anew[j][i] - A[j][i]);
    }
  }

#pragma acc kernels
  for( int j = 1; j < n-1; j++) {
    for( int i = 1; i < m-1; i++ ) {
      A[j][i] = Anew[j][i];
    }
  }

  iter++;
}
```

Copy A in at beginning of loop, out at end. Allocate Anew on accelerator

OpenACC example: Jacobi iteration – second attempt

SDSC Comet CPU: Intel Xeon E5-2680 v3 GPU: NVIDIA Tesla K80 (using single GPU)

Execution	Time (s)	Speedup
CPU 1 OpenMP thread	69	--
CPU 2 OpenMP threads	36	1.92x
CPU 4 OpenMP threads	23	3.14x
CPU 6 OpenMP threads	17	4.06x
OpenACC GPU	5	3.4x

Compiler:
pgcc 17.5-0

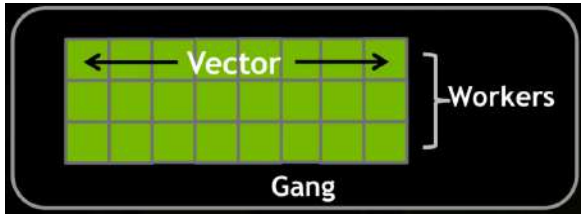
CPU flags:
-fastsse -O3 -mp [-Minfo=mp]

GPU flags:
-acc [-Minfo=accel]

CPU Speedup vs. 1 CPU core

GPU Speedup vs. 6 CPU cores

More OpenACC



- OpenACC gives us more detailed control over parallelization
  - Via **`gang`**, **`worker`**, and **`vector`** clauses
  - Gang corresponds to block, shares resources such as cache, streaming multiprocessor etc)
  - Vector threads work in lockstep (warp)
  - Workers compute a vector, correspond to threads

- By understanding more about OpenACC execution model and GPU hardware organization, we can get higher speedups on this code

- By understanding bottlenecks in the code via profiling, we can reorganize the code for higher performance

More OpenACC

Finding and exploiting parallelism in your code

- (Nested) for loops are best for parallelization
- Large loop counts needed to offset GPU/memcpy overhead
- Iterations of loops must be independent of each other
  - To help compiler: **`restrict`** keyword (C), **`independent`** clause
- Compiler must be able to figure out sizes of data regions
  - Can use directives to explicitly control sizes
- Pointer arithmetic should be avoided if possible
  - Use subscripted arrays, rather than pointer-indexed arrays.
- Function calls within accelerated region must be inlineable.

More OpenACC

Tips and Tricks

- (PGI) Use time option to learn where time is being spent via compiler flag
  `-ta=nvidia,time`
  or use environment variable at run time
  `export PGI_ACC_TIME=1`
- Eliminate pointer arithmetic
- Inline function calls in directives regions
  (PGI): `-Minline` or `-Minline=levels:N`
- Use contiguous memory for multi-dimensional arrays
- Use data regions to avoid excessive memory transfers
- Conditional compilation with `_OPENACC` macro

Exercises on SDSC Expanse – OpenACC

Code samples for this course

- In SI 2021 Github repository
  https://github.com/sdsc/sdsc-summer-institute-2021
  directory **`4.1a_GPU_Computing_and_Programming`**

- Directory **`4.1a_GPU_Computing_and_Programming/openacc-samples`**
  - **`saxpy`**
  - **`laplace-2D`**

If you have not done so, please clone the repository now

- Check the **`README`** files
- Compile and run OpenACC examples
- Check timings of Jacobi iterations on CPU in serial, with OpenMP, and on GPU with OpenACC

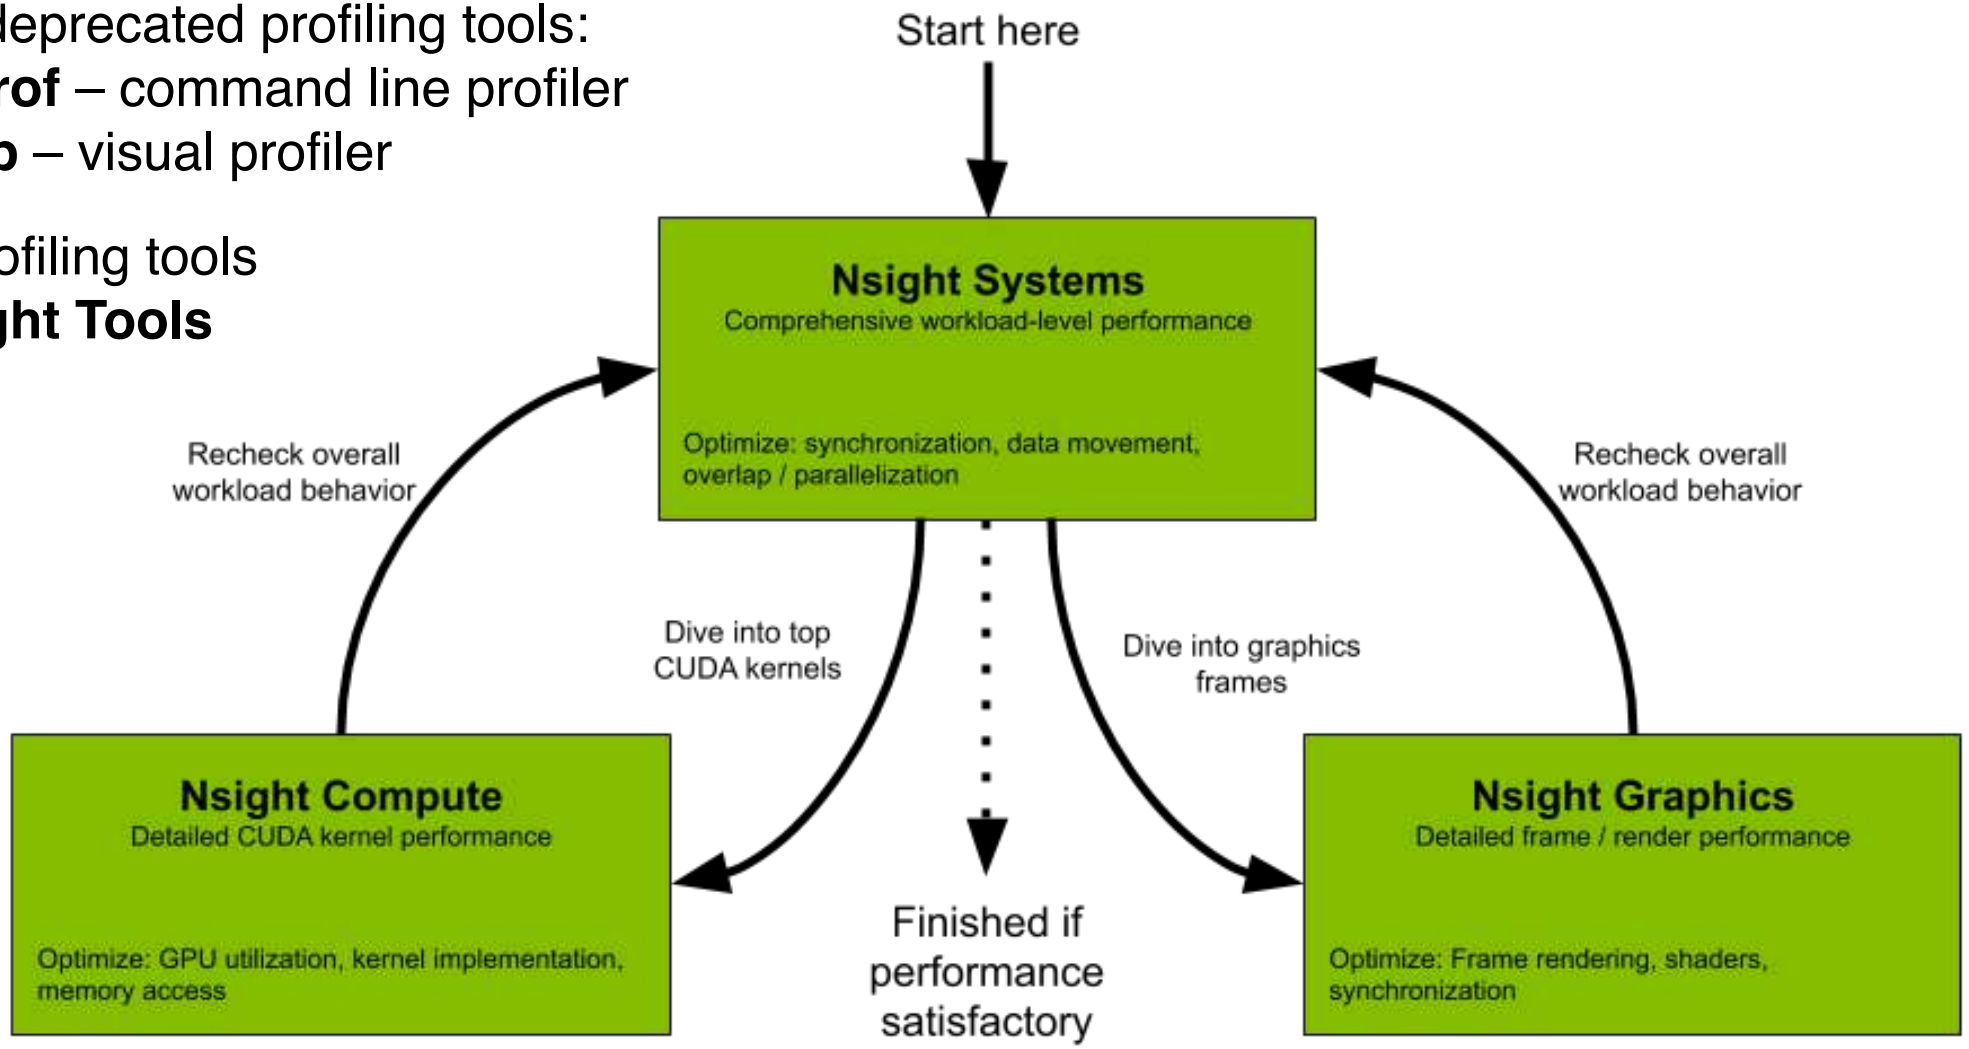
Nvidia profiling tools

Older, deprecated profiling tools:

- **nvprof** – command line profiler
- **nvvp** – visual profiler

New profiling tools

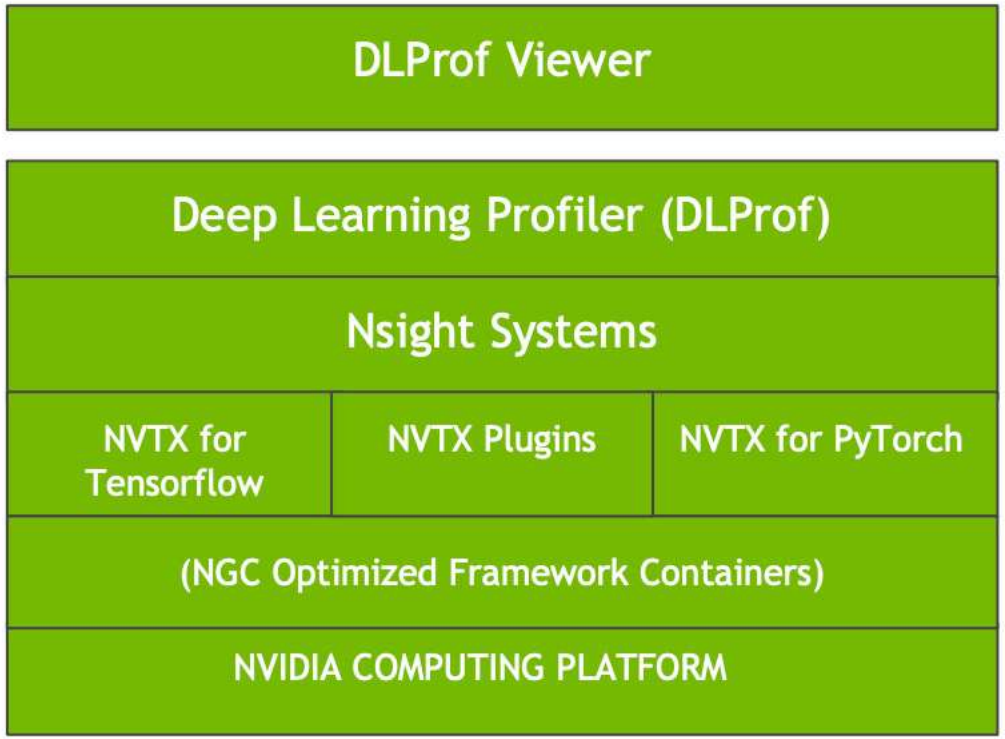
- **Nsight Tools**



Nvidia profiling tools

DLProf: Profiler for Deep Learning applications

- Nsight Systems and Nsight Compute have been built using CUDA Profiling Tools Interface (CUPTI)
- NVTX Nvidia Tools Extension Library is a way to annotate source code with markers
- NVTX markers are used to annotate and focus on sections of code important to the user
- TensorFlow optimized by Nvidia (nvidia-tensorflow) contains support for NVTX markers
- NVTX plugins are are Python bindings for users to add markers easily
- DLProf calls Nsight systems to collect profile data and correlate with the DL model

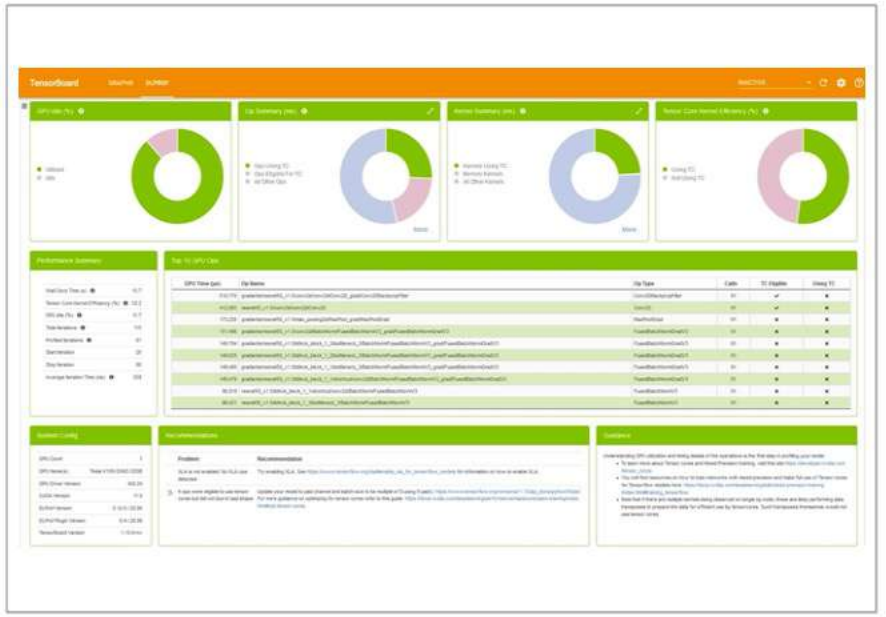


Nvidia profiling tools

DLProf: Profiler for Deep Learning applications

- Are my GPUs being utilized?
- Am I using Tensor Cores?
- How can I improve performance?

FW Support: TF1, TF2, PyT, and TRT
Lib Support: DALI, NCCL



Visualize Analysis and Recommendations

Nvidia profiling tools

DLProf: Profiler for Deep Learning applications

PyTorch

1. TensorFlow and TRT require no additional code modification
2. Profile using DLProf CLI - prepend with ***dlprof***
3. Visualize results with DLProf Viewer

1. Add few lines of code to your training script to enable `nvidia_dlprof_pytorch_nvtx` module
2. Profile using DLProf CLI - prepend with ***dlprof***
3. Visualize with DLProf Viewer

Thanks for listening!

COMPLETE OPENACC API

Kernels Construct

Fortran

```
!$acc kernels [clause …]
    structured block
!$acc end kernels
```

C

```
#pragma acc kernels [clause …]
    { structured block }
```

Clauses

```
if( condition )
async( expression )
```

Also any data clause

Kernels Construct

Each loop executed as a separate kernel on the GPU.

```
!$acc kernels
      do i=1,n
         a(i) = 0.0
         b(i) = 1.0
         c(i) = 2.0
      end do

      do i=1,n
         a(i) = b(i) + c(i)
      end do
!$acc end kernels
```

kernel 1

kernel 2

Parallel Construct

Fortran

```
!$acc parallel [clause …]
    structured block
!$acc end parallel
```

C

```
#pragma acc parallel [clause …]
    { structured block }
```

Clauses

```
if( condition )
async( expression )
num_gangs( expression )
num_workers( expression )
vector_length( expression )
```

```
private( list )
firstprivate( list )
reduction( operator:list )
```

Also any data clause

Parallel Clauses

`num_gangs ( expression )`	Controls how many parallel gangs are created (CUDA `gridDim`).
`num_workers ( expression )`	Controls how many workers are created in each gang (CUDA `blockDim`).
`vector_length ( list )`	Controls vector length of each worker (SIMD execution)
`private( list )`	A copy of each variable in list is allocated to each gang
`firstprivate ( list )`	`private` variables initialized from host
`reduction( operator:list )`	`private` variables combined across gangs

Loop Construct

Fortran

```
!$acc loop [clause …]
    loop
!$acc end loop
```

C

```
#pragma acc loop [clause …]
    { loop }
```

Combined directives

```
!$acc parallel loop [clause …]
!$acc kernels loop [clause …]
```

```
!$acc parallel loop [clause …]
!$acc kernels loop [clause …]
```

Detailed control of the parallel execution of the following loop.

Loop Clauses

`collapse( n )`	Applies directive to the following `n` nested loops.
`seq`	Executes the loop sequentially on the GPU.
`private( list )`	A copy of each variable in list is created for each iteration of the loop.
`reduction( operator:list )`	`private` variables combined across iterations.

Loop Clauses Inside parallel Region

`gang`	Shares iterations across the gangs of the parallel region.
`worker`	Shares iterations across the workers of the gang.
`vector`	Execute the iterations in SIMD mode.

Loop Clauses Inside kernels Region

`gang [( num_gangs )]`	Shares iterations across across at most *num_gangs* gangs.
`worker [( num_workers )]`	Shares iterations across at most *num_workers* of a single gang.
`vector [( vector_length )]`	Execute the iterations in SIMD mode with maximum *vector_length*.
`independent`	Specify that the loop iterations are independent.

Other Syntax

Other Directives

`cache` construct	Cache data in software managed data cache (CUDA shared memory).
`host_data` construct	Makes the address of device data available on the host.
`wait` directive	Waits for asynchronous GPU activity to complete.
`declare` directive	Specify that data is to allocated in device memory for the duration of an implicit data region created during the execution of a subprogram.

Runtime Library Routines

Fortran

```
use openacc
#include "openacc_lib.h"

acc_get_num_devices
acc_set_device_type
acc_get_device_type
acc_set_device_num
acc_get_device_num
acc_async_test
acc_async_test_all
```

C

```
#include "openacc.h"

acc_async_wait
acc_async_wait_all
acc_shutdown
acc_on_device
acc_malloc
acc_free
```

Environment and Conditional Compilation

`ACC_DEVICE` *`device`*	Specifies which device type to connect to.
`ACC_DEVICE_NUM num`	Specifies which device number to connect to.
`_OPENACC`	Preprocessor directive for conditional compilation. Set to OpenACC version
